## How to aggregate experts discount rates: an equilibrium approach

#### Abstract

We address the problem of a social planner who, as in Weitzman (2001), gathers data on experts' discount rates and wants to infer the socially efficient consumption discount rate. We propose an 'equilibrium approach' and we analyse the expression and the properties of the resulting 'equilibrium discount rate. We compare our expression for the discount rate with the different expressions that have been previously proposed in the literature. We analyse the impact of shifts in the distributions of experts discount rates. Finally, we apply our approach to Weitzman (2001)'s data to propose discount rates for public sector Cost-Benefit Analysis, in particular for the long term.

Key-words: consumption discount rate; equilibrium discount rate; experts discount rate; hyperbolic discounting; cost-benefit analysis; gamma discounting; divergence of opinion;

## 1 Introduction

The appropriate social discount rate to apply in public sector cost-benefit analysis is a contentious issue. This is especially true for long term projects, for which financial markets cannot provide any guideline. As Weitzman (2001, p.261) states There does not now exist, nor has ever existed, anything remotely resembling a consensus, even -or, perhaps one should say especially- among the 'experts' on this subject".

or benefits occurring at a given date  $t$ , each expert has proposed a discount In this paper we address the problem of a social planner, who gathers data on experts' discount rates and wants to infer the socially efficient discount rate. More precisely, as in Weitzman (2001), the social planner has consulted a group of experts about the discount rate to apply for costs rate and the problem of the social planner is to aggregate these proposed discount rates into a socially efficient discount rate.

the future of the economy. The (extended) Ramsey equation<sup>1</sup> illustrates 1 2  $R = \rho + \eta \mu - \frac{1}{2} \eta (1 + \eta) \sigma^2$ , where  $\mu$  is the growth rate of the economy and 1 2 the wealth and precautionary savings effect cancel out  $(\mu - \frac{1}{2}(1+\eta)\sigma^2)$ , stationary economy  $(\mu \quad \sigma \quad 0)$  or a risk neutral investor  $(\eta \quad 0)$  or when an important distinction between the *utility* social discount rate and the consumption social discount rate. The former refers to a pure time prefconsumption discount rate. Letting  $R$  denote the consumption discount rate, and  $\rho$  the utility discount rate, Ramsey formula gives the relation  $\eta$  is the elasticity of marginal utility. Apart in the specific settings of a As underlined by e.g. Nordhaus (2007) or Weitzman (2007), there is erence rate that discounts utility. It reflects the level of impatience or, for long time horizon projects, the relative weights of different people or generations. The latter is the rate used to discount future consumption; it is determined by the time preference rate, but also by the anticipations about the distinction and the relation between the utility discount rate and the the two rates differ. In this paper, the rates proposed by the experts, as well as the socially efficient discount rate to be inferred, are consumption discount rates, since they are to be applied to cost-benefit analysis. This is also the case in Weitzman (2001); indeed, as Weitzman makes it clear in

<sup>&</sup>lt;sup>1</sup>The original Ramsey equation (Ramsey, 1928) was derived in a deterministic setting  $(\sigma = 0)$  and is given by  $R = \rho + \eta \mu$ . The extended Ramsey equation corresponds to a direct generalization in a stochastic setting. For the sake of completeness, we rederive it in the Appendix.

the rate of pure time preference on utility"<sup>2</sup>. his questionnaire : What I am here after is the relevant interest rate for discounting real-dollar changes in future goods and services as opposed to

Weitzman (1998, 2001) deal with this problem by adopting a certainty equivalent approach. In this certainty equivalent approach, the social discount factor is taken to be the (arithmetic) average of the discount factors proposed by the experts. Weitzman (1998) derives properties of the certainty equivalent discount rate and in particular, its convergence towards the lowest individual discount rate, whatever the distribution of experts discount rates. Weitzman  $(2001)$  applies this approach to a specific example. Starting from the results of a survey based on the opinions of 2,160 economists about the consumption discount rate, he estimates the distribution of experts discount rates and derives an explicit expression for the certainty equivalent discount rate in this case (Gamma discounting). Gollier (2004) underlines that the approach of Weitzman (1998, 2001) amounts to ranking the projects according to their expected net present value. By adopting the criterion that projects should be ranked according to their expected future value, Gollier (2004) reaches opposite conclusions and concludes that both criteria are arbitrary as they do not rely on realistic preferences of human beings towards risk and time" suggesting that an equilibrium analysis is maybe the cost to be paid to make policy recommendations that have an economic sense.

beliefs  $(\mu_i, \sigma_i)$  about the future growth of the economy. The divergence in i has applied the Ramsey formula and proposed a discount rate  $R<sup>i</sup>$  that corresponds to her own pure time preference rate  $\rho_i$  (or as previously unthe proposed individual discount rates  $R<sup>i</sup>$  stems then from divergence in We propose an approach to aggregate experts' discount rates into a consensus discount rate, which relies on an equilibrium analysis. Our approach is the following. We consider that each expert in the panel has consulted an equilibrium model, calibrating it with her own tastes and beliefs parameters, in order to propose her own discount rate. For instance, expert derlined, to her own conception of intergenerational equity) and her own individual tastes and beliefs. We consider that experts' tastes and beliefs are representative in the sense that each of them represents the tastes and beliefs of a portion of the population. It is then natural to adopt as the

<sup>&</sup>lt;sup>2</sup>Moreover, the fact that the given rates are on average equal to  $4\%$  confirms that the experts actually gave their discount rate for consumption.

spectively to characteristics  $(\rho_1, \mu_1, \sigma_1)$ ,  $(\rho_2, \mu_2, \sigma_2)$  and  $(\rho_3, \mu_3, \sigma_3)$ , and if economy made of one third of agents with characteristics  $(\rho_1, \mu_1, \sigma_1)$ , one third of agents with characteristics  $(\rho_2, \mu_2, \sigma_2)$  and one third of agents with characteristics  $(\rho_3, \mu_3, \sigma_3)$ . This means that we have transformed the probthe discount rate  $R^1$ , the second  $R^2$  and the third  $R^3$  corresponding resocially efficient discount rate the equilibrium discount rate in the economy made of agents with the heterogeneous beliefs and tastes of the experts. For example, if the panel is made of three experts, the first expert proposing we assume that the three experts are equally representative, then we take as the socially efficient discount rate the equilibrium discount rate in an lem of aggregating data on heterogeneous discount rates into the problem of aggregating data on heterogeneous beliefs and tastes.

 $_t$ We can then apply the techniques<sup>3</sup> of Jouini et al. (2008) in order to  $\equiv \frac{t}{A_t}$ average discount rate between date 0 and date t is given by  $R_t \equiv \frac{1}{t} \ln A_t$ obtain the expression of the socially efficient discount rate. If we let  $A_t$ t  $t \equiv \frac{A}{A}$ and the marginal discount rate is given by  $r_t \equiv \frac{A_t}{A_t}$ . We obtain that denote the price at date  $0$  of a zero coupon bond maturing at date  $t$ , the both rates are weighted averages of the individual discount rates. They are both decreasing with time and converging to the lowest individual expert discount rate. These properties hold for both constant and decreasing pure time preference rates.

 $\frac{c^{1-\eta}}{1-\eta}$  with  $\eta$  / risk aversion<sup>4</sup>. The second reason is the central role of logarithmic utility  $\frac{c^{1-\eta}}{1-\eta}$  with  $\eta \neq 1$ ,  $\eta$ In the present paper we consider logarithmic utility functions. There are essentially two reasons for such a restriction. The first reason is analytical tractability. Indeed, as underlined by Rubinstein (1975), "log utility functions are singular in their capacity to cope with heterogeneous beliefs while not imposing unreasonable restrictions on tastes". This choice enables us to obtain simple formula, while considering reasonable levels of functions. Jouini et al. (2008) shows that the log-utility setting is central in the analysis of beliefs heterogeneity: some biases are induced when we deal with power utility function  $\frac{c^{1-\eta}}{1-\eta}$  with  $\eta \neq 1$ , these biases being in opposite directions depending on the position of  $\eta$  with respect to 1. This is then an additional argument in favor of the log-utility setting. Note finally that

<sup>&</sup>lt;sup>3</sup> Jouini et al. (2008) deals with the determination of the equilibrium discount rate in an economy in which agents have heterogeneous beliefs and heterogeneous time preference rates.

<sup>&</sup>lt;sup>4</sup>The case with more general power utility functions would be much more difficult to handle.

the choice of  $\eta$ the choice of  $\eta$  1 is also made in the Stern Review.

We compare our expression for the socially efficient discount rate with other possible functions of the individual discount rates previously considered in the literature. In particular, our formula are different from Weitzman (1998). The equilibrium discount rate coincides with Weitzman (1998, 2001) certainty equivalent discount rate when all experts have the same pure time preference rate. In a more general setting, the discount rates of the more impatient experts are granted a higher weight. A possible interpretation is as follows. When considering its intertemporal rate of substitution, the group must weigh more the agents with a higher shadow price of the intertemporal budget constraint, i.e. the more impatient members of the group. The overweighting of impatient experts discount rates implies that when tastes and beliefs are independent, the equilibrium discount rate is higher than the certainty equivalent discount rate for all horizons.

We determine the explicit expression of the socially efficient discount rate for specific distributions of the experts' discount rates. We consider Gaussian as well as Gamma distributions. We calibrate the model with a Gamma distribution on Weitzman (2001)'s data. Our results suggest using the following approximation of within-period marginal discount rates for long term public pro jects: Immediate Future about 5 per cent; Near Future about 4 percent; Medium Future about 3 percent; Distant Future about 1.5 per cent and Far-Distant Future about 0 per cent. Except for the Far-Distant Future, these rates are slightly higher than those obtained by Weitzman (2001) .

Finally, we determine which concepts of stochastic dominance on the distributions of experts/individual discount rates lead to a clear impact on the equilibrium discount rate. We analyze the impact of standard shifts, like first or second stochastic dominance shifts as well as monotone likelihood ratio dominance shifts. The impact of these shifts are different depending on which discount rate (average or marginal) we consider. Roughly speaking, more pessimism, more patience, more doubt as well as more heterogeneity in individual discount rates reduce the equilibrium discount rate.

Note that our approach also permits to aggregate utility discount rates<sup>5</sup> (pure time discount rates). It suffices to consider the specific case where

<sup>&</sup>lt;sup>5</sup>The problem of aggregating individual utility discount rates has been studied by, among others, Reinschmidt (2002) through a certainty equivalent approach, Nocetti et al. (2008) through a Benthamite approach, Gollier Zeckhauser (2005) through a Pareto optimality approach and Lengwiler (2005) through an equilibrium approach.

aggregating individual *utility* discount rates, the aim of the present paper is to aggregate individual *consumption* discount rates and to do it through an *equilibrium* approach. there is no beliefs heterogeneity. We obtain that the equilibrium utility discount rate is a weighted average of the individual ones. Our formulas are analogous to those of Lengwiler (2005). They coincide with those of Nocetti et al. (2008) and Gollier and Zeckhauser (2005) only for specific choices of Pareto weights. They differ from those in Reinschmidt (2002), in the same way as our formulas for the consumption discount rate differ from those in Weitzman (1998). We emphasize that, while these papers aim at

All proofs are in the Appendix.

## 2 Equilibrium discount rate

Let us consider *n* experts, who propose different discount rates  $(R<sup>i</sup>)$  for cost-benefit analysis of public projects as in Weitzman (2001).

the extended Ramsey equation, the consumption discount rate  $R<sup>i</sup>$  proposed We assume that the discount rate proposed by expert  $i$  for costs or benefits occurring at date  $t$  comes from a general equilibrium model with  $log$  utility and lognormal aggregate consumption at date  $t$ . According to by expert  $i$  is given by

$$
R^i \quad \rho_i + \mu_i \quad \sigma_i^2
$$

where  $\rho_i > 0$ ,  $\mu_i$  and  $\sigma_i^2$  are respectively the pure time preference rate, the the model. The divergence on the discount rates  $(R<sup>i</sup>)$  results then from mean and the variance (by unit of time) of the distribution of the growth rate of aggregate consumption that the expert uses in order to calibrate divergence on these parameters.

Assuming that experts differ in their expectation about the growth rate is fairly natural. Indeed, the expected growth rate reflects the opinion about the future. It suffices to look at experts forecasts to realise that there is no consensus about the future of the economy. Indeed, forecasting for the coming year is already a difficult task. It is natural that forecasts for the next century/millennium are sub ject to potentially enormous divergence. It is doubtful that agents or economists currently have a complete understanding of the determinants of long term economic evolutions. It is also natural to assume that experts differ in their pure time preference rate since it may reflect their point of view about intergenerational equity as well as

one's level of impatience. The important debate among economists (and also among philosophers) on the notion of intergenerational equity is an illustration of this possible divergence. Some will argue that intergenerational choices should be treated as intertemporal individual choices leading to weigh more present welfare. Others will argue that fundamental ethics require intergenerational neutrality and that the only ethical basis for placing less value on the welfare of future generations is the uncertainty about whether or not the world will exist and whether or not these generations will be present.

The problem now is to determine how to aggregate these experts' recommended discount rates into a consensus discount rate. We consider that the panel experts' tastes and beliefs reflect those of the population. We shall then consider a complete markets economy with heterogeneous agents endowed with the beliefs and tastes chosen by the experts and we shall adopt the equilibrium discount rate in this economy as our consensus discount rate. There is no specific reason to discriminate between the experts, hence we suppose that each expert is representative of the same proportion of the agents in the economy and that all the agents have the same initial endowment.

To summarise, we have

- $N$  groups of agents,
- $w_i \equiv$  relative size of group i,
- $\rho_i \equiv$  pure time preference rate of the agents in group  $i$ ,
- $t \equiv$  the time at which a cost or benefit is incurred, relative to the present time,
- $(\frac{1}{2}\sigma^2)t$   $\sigma^2t$  = group i's approximated distribution 2 •  $\ln \mathcal{N}((\mu_i \quad \frac{1}{2}\sigma_i^2)t, \sigma_i^2 t) \equiv \text{group } i\text{'s anticipated distribution}^6 \text{ of aggregate}$ consumption at date  $t$ ,
- log utility functions,
- $R^i \equiv \rho_i + \mu_i \quad \sigma_i^2$ , the individual discount rate for agents in group i, was made of group  $i$  agents only. i.e. the equilibrium discount rate that would prevail if the economy

<sup>&</sup>lt;sup>6</sup>This is the case for instance if aggregate consumption is a geometric Brownian motion with drift  $\mu_i$  and volatility  $\sigma_i$ . We will in Section 4 consider a more general setting with general distributions for aggregate consumption. The formulas are then less easy to handle.

The weights  $w_i$  model then the distribution of agents' characteristics in the economy, which also correspond by construction to the distribution of experts characteristics.

### 2.1 Expression of the equilibrium discount rate and properties

 $_t$ t. We denote by  $r_t \equiv \frac{A'_t}{A_t}$  $\frac{1}{t}$   $\int_0^t$ at date 0 of \$1 at date t. We denote by  $R_t \equiv \frac{1}{t} \ln A_t$  the discount rate for We denote by  $A_t$  the equilibrium discount factor for horizon  $t$ , i.e. the price would yield the discount factor  $A_t$ . We denote by  $r_t \equiv \frac{A_t}{A_t}$  the marginal We have  $R_t$ We have  $R_t = \frac{1}{t} \int_0^t r_s ds$ . Marginal and average rates of discount coincide marginal discount rate  $r^i$  coincides with the individual discount rate  $R^i$ . horizon  $t$ , i.e. the rate which if applied constantly for all intervening years discount rate for horizon  $t$ , i.e. the rate of change of the discount factor. when the discount rate is constant. In particular, for all  $i$ , the individual However, the distinction between the two notions of discount rates can become important when the discount rate is time dependent (Groom et al., 2005).

average discount rate  $R_t$  is given by We easily get, as in Jouini et al. (2008, Proposition 5.1), that the

$$
R_t \equiv \frac{1}{t} \ln \sum_{i=1}^{N} \frac{w_i \rho_i}{\sum_{j=1}^{N} w_j \rho_j} \exp \ R^i t,\tag{1}
$$

 $R_{\infty}$ continuum of agents, and general distributions for aggregate consumption<sup>7</sup>.  $R_{\infty}$  in  $\int_i R^i$ . Note that our setting is slightly different from the setting in (1) at the beginning of the Appendix. Moreover, we will show in Section 4 that the formula for  $R_t$  in Equation (1) remains valid in a very general that it decreases with  $t$  and that it converges to the lowest proposed rate Jouini et al. (2008). Indeed, in Jouini et al. (2008), aggregate consumption follows a specific diffusion process. However, the proofs remain essentially the same. For the sake of completeness, we provide the proof of Equation Arrow Debreu setting, with continuous or discrete time, a finite number or a

Analogously, we easily obtain the following results on the marginal discount rate.

<sup>&</sup>lt;sup>7</sup>In a more general setting, the individual discount rates  $R_t^i$  are not given by the Ramsey formula and may then be dependent upon  $t$ .

Proposition 1 1. The equilibrium marginal discount rate is given by

$$
r_t \equiv \sum_{i=1}^{N} \frac{w_i \rho_i \exp(-r^i t)}{\sum_{j=1}^{N} w_j \rho_j \exp(-r^j t)} r^i.
$$
 (2)

 $\mu_i$   $\mu, \sigma_i$   $\sigma$ 2. In the case of homogeneous beliefs  $(\mu_i, \mu, \sigma_i, \sigma_j)$ , the equilibrium marginal discount rate is given by

$$
r_t \equiv \sum_{i=1}^{N} \frac{w_i \rho_i \exp(-\rho_i t)}{\sum_{j=1}^{N} w_j \rho_j \exp(-\rho_j t)} \rho_i + \mu \quad \sigma^2.
$$
 (3)

discount rate is given by the lowest individual discount rate, i.e.  $r_{\infty}$  $\inf_i r^i \quad R_\infty.$ 3. The discount rate  $r_t$  decrease with t, and the asymptotic equilibrium

constraint, i.e. the more impatient members of the group<sup>8</sup>. except in the case of homogeneous pure time preference rates, i.e.  $\rho_i - \rho$ for all  $i$ , our expressions for the rates are different from those of Weitzman As in the certainty equivalent approach of Weitzman (1998), the consensus discount factors obtained through our equilibrium approach are averages of the individual discount factors proposed by the experts. However, (1998). There is a bias towards the more impatient agents in the consensus equilibrium discount rates. A possible interpretation is as follows. When considering its intertemporal rate of substitution, the group must weigh more the agents with a higher shadow price of the intertemporal budget

to the least confident agent (highest  $\sigma_i^2$ ) when there is no pure time prefermost patient agent (lowest  $\rho_i$ ) when there is no beliefs heterogeneity, or to the most pessimistic agent (lowest  $\mu_i$ ) when there is no pure time preference As far as asymptotic properties are concerned, we obtain, as in Jouini et al. (2008) that the relevant rate in the long run is given by the lowest individual discount rate. This rate corresponds to the discount rate of the rate heterogeneity and all the agents have the same volatility parameter or ence rate heterogeneity and all the agents have the same drift parameter. Moreover, the equilibrium approach leads to decreasing discount rates, not only utility discount rates, but also consumption discount rates. As in the

dence/doubt in the form of a lower/higher  $\sigma_i^2$  have no impact on the relative weights, <sup>8</sup>Note that optimism/pessimism in the form of a higher/lower  $\mu_i$  or overconfi but this might be due to the specific logarithmic utility function.

certainty approach of Weitzman (1998), this leads to use lower discount rates for long term projects in a cost-benefit analysis.

 $\sum_{i}^{N} \frac{w_i \rho_i \exp(-\rho_i \mathrm{i} \theta_i)}{\sum_{j=1}^{N} w_j \rho_j \exp(-\rho_i \mathrm{i} \theta_j)}$  $\equiv \sum_{i=1}^{N} \frac{1}{\sum_{j=1}^{N} w_j \rho_j \exp(-\rho^j)}$ In the case of homogeneous beliefs, Equation (3) involves the covariance between  $\rho_i$  and exp  $\rho_i t$  as in Lengwiler (2005). Equation (3) also gives us  $w_i \rho_i \exp \rho_i t$  whereas they are given by  $\lambda_i \exp \rho_i t$  in Gollier and Zeckhauser (2005) or Nocetti et al. (2008), where the  $(\lambda_i)$  are Pareto weights  $\exp(-\rho_i t)$  $\rho \equiv \sum_{i=1}^{N} \frac{w_i \rho_i \exp(-\rho_i t)}{\sum_{i=1}^{N} w_i \rho_i \exp(-\rho_i t)} \rho_i$ our weights in the weighted averages of the  $\rho_i$  are given by the quantities social utility discount rate if the Pareto weights were proportional to  $w_i \rho_i$ .  $w_i \rho_i \exp(-\rho_i t)$ the expression for the consensus utility discount rate  $\rho \equiv \sum_{i=1}^{N} \frac{w_i \rho_i \exp(-\rho_i t)}{\sum_{i=1}^{N} w_i \rho_i \exp(-\rho_i t)} \rho_i$ . Although of the same nature, this expression is slightly different from the one obtained through the Pareto optimality of Gollier and Zeckhauser (2005) or the Benthamite approach of Nocetti et al. (2008). Indeed, chosen by the social planner. Notice that this means that our equilibrium approach and the Pareto/Benthamite approach would lead to the same

### 2.2 Comparison with other formula for the socially efficient discount rate

The following proposition clarifies the relation between our socially efficient discount rate and the different expressions that have been provided in the literature.

Proposition 2 1. The equilibrium discount rate is lower than the pure time preference weighted arithmetic average of the individual discount rates, i.e.

$$
R_t \le \sum_{i=1}^N \frac{w_i \rho_i}{\sum_{j=1}^N w_j \rho_j} R^i \text{ and } r_t \le \sum_{i=1}^N \frac{w_i \rho_i}{\sum_{j=1}^N w_j \rho_j} r^i. \tag{4}
$$

2. If the tastes and beliefs characteristics  $\rho_i$  and  $b_i \equiv \mu_i$   $\sigma_i^2$  are intastes characteristics  $\rho_i$  have higher beliefs characteristics  $b_i$ , then the dependent or if they are comonotonic, i.e. individuals with higher equilibrium discount rate is higher than an average of the individual discount rates, i.e.

$$
R_t \geq \frac{1}{t} \ln \sum_{i=1}^{N} w_i \exp \ R^i t. \tag{5}
$$

3. If the tastes and beliefs characteristics  $\rho_i$  and  $b_i \equiv \mu_i \quad \sigma_i^2$  are independent, then the equilibrium marginal discount rate is higher than an average of the individual marginal discount rates, i.e.

$$
r_t \ge \sum_{i=1}^N \frac{w_i \exp \ r^i t}{\sum_{j=1}^N w_j \exp \ r^j t} r^i.
$$
 (6)

by the pure time preference rates  $\rho_i$  hence higher weights are granted to Equation (4) means that, as expected, the discount rate to use is lower discount rates. Moreover, Equations (5) and (6) imply that, when tastes than the simple arithmetic average (with the same weights) of the individual and beliefs characteristics are independent, our discount rates are higher than those of Weitzman (2001). This is intuitive since our weights are given higher individual discount rates.

## 3 Specific Distributions and Dominance Properties

of the experts discount rates  $(R<sup>i</sup>)$ . Equation (1) as well as Proposition 1 experts discount rates  $(R<sup>i</sup>)$  or  $(r<sup>i</sup>)$ . provide the expression of the discount rates  $R$  and  $r$  as a function of the Let us now determine the equilibrium discount rate for specific distributions

#### 3.1 Gaussian and Gamma distributions

continuum of agents<sup>9</sup>. The problem is that according to Equations  $(1)$  and (2), we need to make extra assumptions on the joint distribution of  $(\rho_i, R^i)$ in order to determine the discount rates  $R$  and  $r$ . We whall consider continuous sets of experts. It is easy to show that the expression of the discount rates remains the same in the setting with a

2  $\rho_i$   $\rho$ , and with a normal distribution  $\mathcal{N}(m, v^2)$  on the beliefs parameters 2 2  $N(\rho+m, v^2)$  and we easily obtain that  $R_t$   $\rho+m=\frac{2}{2}$  $\rho_i$  $i \mu_i \sigma_i^2$ . The discount rates  $(R^i)$  $\mu$   $\rho + m$   $\frac{v}{\epsilon}$  $(R^i)$  $(\rho + m, v^2)$  and we easily obtain that  $R_t$   $\rho +$  $b_i$   $\mu_i$   $\sigma_i^2$ . The discount rates (R)  $(\rho + m, v^2)$  and we easily obtain that  $R_t$   $\rho + m$   $\frac{v^2}{2}t$ . Consider first the case with homogeneous pure time preference rates The discount rates  $(R<sup>i</sup>)$  then follow a normal distribution and we easily obtain that  $R_t$   $\rho + m$   $\frac{v^2}{2}t$ . Reinschmidt (2002) obtains a similar formula for the consensus utility discount rate when the individual utility discount rates follow a normal distribution.

<sup>9</sup> See Section 4 for a proof in a more general setting.

Suppose now that utility discount rates and beliefs are independently<sup>10</sup> and gamma distributed. We obtain the following result.

<sup>11</sup> with  $\rho_i \sim \gamma(\alpha_1, \beta_1)$  and  $b_i \sim$ **Proposition 3** If pure time preference rates  $\rho_i$  and beliefs  $b_i$   $\mu_i$   $\sigma_i^2$  $(\alpha_1, \beta_1)$  and  $b_i \sim \gamma(\alpha_2, \beta_2)$ ,  $_i$  and veneps  $o_i$   $\mu_i$   $\sigma_i$  $\gamma_i \sim \gamma(\alpha_1, \beta_1)$  and  $\alpha_i$  $\rho_i$  and beliefs  $b_i$   $\mu_i$   $\sigma$  $\rho_i \sim \gamma(\alpha_1, \beta_1)$  and  $b_i \sim \gamma(\alpha_2, \beta_2)$ , If pure time preference rates  $\rho_i$  and beliefs  $b_i$   $\mu_i$   $\sigma_i^2$  are independently distributed<sup>11</sup> with  $\rho_i \sim \gamma(\alpha_1, \beta_1)$  and  $b_i \sim \gamma(\alpha_2, \beta_2)$ , then

A decrease in the mean  $m_2$  or an increase in the variance  $v_2^2$  of the  $m_1$  of the individual pure time preference rates  $(\rho_i)$ . An increase in the variance  $v_1^2$  of the individual pure time preference rates  $(\rho_i)$  decreases the individual beliefs  $(b_i)$  decreases the marginal discount rate  $r_t$  (hence the discount rate  $R_t$ ). The same result occurs with a decrease in the mean marginal discount rate  $r_t$  for t large enough.

decreases the marginal discount rate and an increase in the variance  $v^2$  of same value. A decrease in the mean m of the individual discount rates  $(R<sup>i</sup>)$ the individual discount rates  $(R<sup>i</sup>)$  decreases the marginal discount rate  $r_t$ count rates  $R^i$  or  $r^i$  is a sufficient statistics for the equilibrium discount tions with the same parameter  $\beta$ , the distribution of the individual disfor  $t$  large enough. When beliefs and tastes are independent and follow gamma distriburate. As in Weitzman (2001), experts discount rates then follow a Gamma distribution. As shown in the previous section, our equilibrium discount rates are higher than Weitzman (2001)'s discount rates but converge to the

<sup>10</sup> We focus on the case of independent distributions as a central case; explicit formulas may also be derived in the case of a given correlation between pure time preference rates and beliefs.

 $\frac{\alpha}{\alpha}x^{\alpha-1}\exp(-\frac{\alpha}{2}x)$ and  $\frac{\alpha}{\beta^2}$ . <sup>11</sup>Recall that the density function of a gamma distribution  $\gamma(\alpha, \beta)$  is given by  $\frac{\beta^{\alpha}}{\Gamma(\alpha)}x^{\alpha}$  1 exp( $-\beta x$ ). Its mean m and its variance  $v^2$  are respectively given by  $m = \frac{\alpha}{\beta}$ 

#### 3.2 Calibration on Weitzman (2001)'s data

 $\left(m^2 \quad m \quad m^2 \quad m\right)$  $i_i \sim \gamma(\alpha_1, \beta_1)$  and  $b_i \sim \gamma(\alpha_2, \beta_2)$  $\frac{2}{1} \equiv$  $\times$  10 °, 1.30  $\times$  10 °, 2.83  $\times$  10 °,  $7.09 \times$ 1 1 2 2 1 2  $\frac{1}{2}$  $2, 2, 2$ 2  $2, 2, 2$ m v m Weitzman(2001)'s sample. We further impose that  $\frac{m_1}{v_1} - \frac{m_2}{v_2}$  (same ratio β 1  $\alpha_2$  and  $\overline{\beta}$ m m m v m v m  $\boldsymbol{v}$ m  $\left( \frac{1}{2} \sqrt{2}, \frac{\sqrt{2}}{2}, \frac{\sqrt{2}}{2}, \frac{\sqrt{2}}{2}, \frac{\sqrt{2}}{2}, \frac{\sqrt{2}}{2} \right)$  $v_1 + m_2$  m and  $v_1^2 + v_2^2$  v<sup>2</sup> where m and  $v^2$  $1, \rho_1, \alpha_2, \rho_2$  $\{1, v_1^2, m_2, v_2^2\}$  (1.16  $\times$  10<sup>-2</sup>, 1.30  $\times$  10<sup>-4</sup>, 2.83  $\times$  10<sup>-2</sup>, 7.69  $\times$  10<sup>-4</sup>  $\mu$   $\sigma^2$  can be in- $\rho_i \sim \gamma(\alpha_1, \beta_1)$  and  $b_i \sim \gamma(\alpha_2, \beta)$  $m_1 + m_2$  m and  $v_1^2 + v_2^2$  v where m and v  $\alpha_1$   $\alpha_2$  and  $\frac{\beta_1}{\beta_1}$   $\frac{m_2}{m_1} \equiv \lambda$ , for some positive  $\lambda$ . Note that for  $\lambda$  $\alpha_1, \beta_1, \alpha_2, \beta_2 \big) \, \, \left( \frac{m^2}{2v^2}, \frac{m}{v^2}, \frac{m^2}{2v^2}, \frac{m}{v^2} \right),$ likelihood with respect to the parameter  $\lambda$  to choose the best calibration.  $\lambda = 0.4116 \,\, \mathrm{hence} \,\, \left( \alpha_1, \beta_1, \alpha_2, \beta_2 \right) = (1.043, 89.454, 1.043, 36.8)$  $m_1, v_1^2, m_2, v_2^2)$   $(1.16 \times 10^{-2}, 1.30 \times 10^{-4}, 2.83 \times 10^{-2}, 7.6$ rate among experts equal to  $1.16\%$  and a median equal to  $0.67\%$  and a meter (about the growth of the economy) equal to 2.83% and a median equal to 2%. More precisely, the belief parameter  $b \mu \sigma^2$  can be in- $(\alpha_1, \beta_1)$  and  $b_i \sim \gamma(\alpha_2, \beta_2)$  $+m_2$  m and  $v_1^2 +$ to  $\alpha_1$  and  $\frac{\beta_1}{\beta_1}$   $\frac{m_2}{m_1} \equiv \lambda$ , for some positive  $\lambda$ . Note that for  $\lambda$  1, we get  $(\alpha_1, \beta_1, \alpha_2, \beta_2)$ 0.4116 hence  $(\alpha_1, \beta_1, \alpha_2, \beta_2)$   $(1.043, 89.454, 1.043, 36.819)$  $(m_1, v_1^2, m_2, v_2^2)$   $(1.16 \times 10^{-2}, 1.30 \times 10^{-4}, 2.83 \times 10^{-2}, 7.69 \times 10^{-4}).$ We now calibrate this model with two independent gamma distributions and  $b_i \sim \gamma(\alpha_2, \beta_2)$  on Weitzman (2001)'s data. We impose that  $m_1 + m_2$  m and  $v_1^2 + v_2^2$  v<sup>2</sup> where m and  $v_1^2$  respectively denote the mean and the variance of the individual discount rates computed on between mean and standard deviation for both distributions), which leads get  $(\alpha_1, \beta_1, \alpha_2, \beta_2)$   $(\frac{m^2}{2v^2}, \frac{m}{v^2}, \frac{m^2}{v^2}, \frac{m}{v^2})$ , which corresponds to the calibration in Weitzman (2001). We have then a family of stastistical models that contains Weitzman  $(2001)$ 's statistical model and we maximize the log-We obtain  $\lambda$  0.4116 hence and  $(m_1, v_1^2, m_2, v_2^2)$   $(1.16 \times 10^{-2}, 1.30 \times 10^{-4}, 2.83 \times 10^{-2}, 7.69 \times 10^{-4})$ . To summarise, the best calibration corresponds to a gamma distribution on the individual pure time preference rates with an average time preference gamma distribution on the individual beliefs with an average belief paraterpreted as a risk adjusted growth rate. The values we obtain are then reasonable values for both an average pure time preference rate and an average risk-adjusted growth rate. Stern report considers values for the pure time preference rate (utility discount rate) between 0.1 and 1.5 and values for the growth rate ranging from 0 per cent to 6 per cent. Arrow (1995) states that the pure time preference rate should be about 1% and surveying the evidence, the HM Treasury's Green Book (2003) suggests a long run growth rate of 2.1 per cent.

Figure 1 represents the log-likelihood as a function of  $\lambda$ . Figure 2 rep- $\lambda$  that maximizes the log-likelihood ( $\lambda$  0.4116) as well as the empirical  $0.4116$ ) as well as the empirical resents the distribution of the individual discount rates for the parameter distribution and Weitzman (2001)'s distribution. Figure 3 represents the corresponding marginal discount rate curve and compares it to the discount rate curve of Weitzman (2001). Table 1 presents the corresponding recommended sliding-scale discount rates: Immediate Future about 5 per cent; Near Future about 4 percent; Medium Future about 3 percent; Distant Future about 1.5 per cent and Far-Distant Future about 0 per cent.

#### 3.3 Dominance properties

Y X such that  $f_X(x)f_Y(y) \leq f_X(y)f_Y(x)$  for all  $y \leq x$  (roughly speaking, the f ratio  $\frac{f_Y}{f_X}$  is nondecreasing). to obtain a clear impact on the socially efficient marginal discount rate  $r$ , and is defined as follows: a random variable  $Y$  dominates a random variable X, if X and Y have densities with respect to some dominating measure  $\nu$ In the specific setting of Gamma distributions considered in Proposition 3, we have seen the impact of an increase in the mean and in the variance of the distribution of individual discountrates on the socially efficient discount rates. The impact was the same for the average and for the marginal discount rates. We now analyze in a more general setting which shifts on the distribution of individual discount rates have a clear impact on the socially efficient discount rates. We consider First and Second Stochastic Dominance shifts, as defined in e.g. Rothschild and Stiglitz (1970). In order we also consider Monotone Likelihood Ratio dominance (MLR) shifts. This concept of dominance has been studied by Landsberger and Meilijson (1990)

- Proposition 4  $\rho_i$ , then a FSD (resp. SSD) shift in the distribution of  $(R^i)$  increases the discount rate  $R_t$  for all horizons. 1. If all the agents have the same time preference rate
	- 2. If all the agents have the same time preference  $\rho_i$ , then a MLR shift in the distribution of the  $(r<sup>i</sup>)$  increases the marginal discount rate  $r<sub>t</sub>$ for all horizons.
	- tribution of the  $(R<sup>i</sup>)$  increases the discount rate  $R<sub>t</sub>$  for all horizons. 3. If all the agents have the same beliefs, then a MLR shift in the dis-

Proposition 4 makes it clear which concepts of dominance (corresponding to the notions of pessimism, doubt, patience, or heterogeneity) one should consider in order to have a clear impact on the discount rates. Roughly speaking, it means that a country where experts are more pessimistic and/or exhibit more doubt about future growth and/or have lower pure time preference rates (more patient or more altruistic with respect to future generations) should apply a lower discount rate for cost-benet analysis. More heterogeneity in experts beliefs about future growth rates also leads to lower discount rates.

equally large groups<sup>12</sup> with discount rates of  $2\%$ ,  $3\%$  and  $4\%$ . In a sec-1 2 1 6 1 growth rates but their proportion in the population is  $\frac{1}{2}$ ,  $\frac{1}{6}$  and  $\frac{1}{3}$ . Popula-1 10 8 10 1 their proportion in the population is  $\frac{1}{10}$ ,  $\frac{8}{10}$  and  $\frac{1}{10}$ . Populations (A) and ulation respectively equal to  $w_1$ ,  $w_2$  and  $w_3$ . The population (E) is more patient (in the sense of the MLR) if  $w_3 < w_2 < w_1$ . In this case, the discount in population (A) are given by  $[1.5, 2.5]$ ,  $[2.5, 3.5]$  and  $[3.5, 4.5]$  while in a are given by  $[1; 3]$ ,  $[2; 4]$  and  $[3; 4]$ . There is more doubt in population  $(D)$ consider two populations  $(E)$  and  $(F)$ . In population  $(E)$ , there are three More precisely, suppose that in one population, say  $(A)$ , we have three ond population (B), there are also three groups with the same anticipated tion (B) is more pessimistic than population (A) (in the sense of the FSD) and the discount rate to apply is lower for  $(B)$ . In a third population  $(C)$ , there are three groups with anticipated growth rates 1%, 3% and 5% and (C) have the same average level of pessimism but population (C) is more heterogeneous (in the sense of the SSD) than population (A) and the discount rate to apply is lower for (C). Let us assume now that experts provide forecasts with a 95% condence interval. Let us assume that these intervals fourth population (D) also with three equally large groups, these intervals and the discount rate to apply is then lower for  $(D)$ . The MLR (monotone likelihood ratio) dominance is stronger than the FSD dominance. Let us equally large groups of experts with pure time preference rates respectively equal to 0.5%,  $1\%$  and 1.5%. In population (F) there are also three groups with the same pure time preference rates but with proportions in the poprate to apply for cost-benefit analysis is lower for population  $(E)$ .

## 4 Extensions

In this section, we examine two possible extensions: more general subjective and objective distributions for aggregate consumption and time dependent pure time preference rates.

#### 4.1 General distributions for aggregate consumption

We first show that Proposition 1 remains valid in a very general complete markets Arrow-Debreu setting. Time can be continuous or discrete. We

<sup>&</sup>lt;sup>12</sup>In this paragraph, for simplicity, we refer to groups and their size instead of experts and the size of the population that they represent.

 $Q_t^i$  that represents the distribution of date  $t$  aggregate consumption from preference rate  $\rho_i$ , a share of total wealth  $w_i$  and a log-utility. set of agents is represented by a measured space  $([0,1], \nu)$ . Furthermore consumption. It suffices to assume that agent  $i$  has a probability measure agent  $i$  point of view. As in previous sections, agent  $i$  has a pure time allow for a finite number or a continuum of agents. For this purpose, the we do not need to assume specific individual distributions for aggregate

**Proposition 5** Let us consider a model with a measured space  $([0,1], \nu)$ of log-utility agents that have pure time preference rates  $(\rho_i)$ , wealth shares  $(w_i)$  and date t probability measures  $Q_t^i$ . We assume that all these probabilities are equivalent, i.e. the agents agree on the events of zero probability. The equilibrium discount rate is then given by

$$
R_t \equiv \frac{1}{t} \ln \int_0^1 \frac{w_i \rho_i}{\int_0^1 w_j \rho_j d\nu(j)} \exp\left(-R_t^i t\right) d\nu(i) \tag{7}
$$

where  $R_t^i$  is the equilibrium discount rate that would prevail if the economy was made of agent i only.

is the fact that the individual discount rates  $R_t^i$  may depend upon<sup>13</sup> t. proportional to  $w_i \rho_i$ . The only difference with the setting of Equation (1) In such a general setting, the equilibrium discount rate is still a weighted average of the individual discount rates, and as previously, the weights are

#### 4.2 Time dependent pure time preference rates

 $\frac{1}{t} \int_0^t \rho_i(s) ds + \mu_i \quad \sigma_i^2$ es  $(\rho_i(t))$ . We then have  $R_t^i = \frac{1}{t}$ <br><sup>2</sup> We obtain the following ex t the preference rates  $(\mu_i(t))$ , we then have  $\mu_t = \frac{1}{t} \int_0^t \mu_i(s) ds + \mu_i = o_i$ <br> $\mu_i = \rho_i(t) + \mu_i = \sigma_i^2$ . We obtain the following expression for the soc  $(\rho_i(t))$ . We then have  $R_t^i = \frac{1}{t} \int_0^t \rho_i(s) ds +$  $(t) +$  $\rho_i(t)$ ). We then have  $R_t^i = \frac{1}{t} \int_0^t \rho_i(s) ds + \mu_i \quad \sigma$  $r_t^i$   $\rho_i(t) + \mu_i$   $\sigma$ It is also easy to adapt our approach to the case with time-dependent pure time preference rates  $(\rho_i(t))$ . We then have  $R_t^i = \frac{1}{t} \int_0^t \rho_i(s) ds + \mu_i \sigma_i^2$  and . We obtain the following expression for the socially efficient discount rate.

Proposition 6 If agents have time-dependent positive pure time preference rates  $(\rho_i(t))$ , wealth shares  $(w_i)$  and date t distributions for aggregate

the same as in Equation  $(1)$ , replacing sums by integrals. 13 In particular, if aggregate consumption is lognormal, then the individual discount rates are time independent, and the expression for the socially efficient discount rate is

 $\mathcal{N}((\mu_i-\frac{1}{2}%$ 2 consumption  $\ln \mathcal{N}((\mu_i - \frac{1}{2}\sigma_i^2)t, \sigma_i^2t)$ , the equilibrium discount rates are given by

$$
R_t \equiv \frac{1}{t} \ln \sum_{i=1}^{N} \frac{w_i \overline{\rho}_i}{\sum_{i=1}^{N} w_j \overline{\rho}_j} \exp\left(-R_t^i t\right) \tag{8}
$$

$$
r_t \equiv \sum_{i=1}^{N} \frac{w_i \overline{\rho}_i \exp\left(-\int_0^t r_s^i ds\right)}{\sum_{i=1}^{N} w_j \overline{\rho}_j \exp\left(-\int_0^t r_s^i ds\right)} r_t^i \tag{9}
$$

 $\frac{1}{t}\int_0^t \rho_i(s)ds + \mu_i \sigma_i^2, r_t^i \rho_i(t) + \mu_i \sigma_i^2 \text{ and } \overline{\rho}_i \left(\int_0^\infty \exp\left(-\int_0^t \rho_i(s) ds\right) dt\right)$  $R^i_t - \frac{1}{t} \int_0^t \rho_i(s) ds + \mu_i \sigma_i^2, r^i_t - \rho_i(t) + \mu_i \sigma_i^2 \text{ and } \overline{\rho}_i - \left( \int_0^\infty \exp \left( - \int_0^t \rho_i(s) ds \right) dt \right)^{-1}.$ If the pure time preference rates  $(\rho_i(t))$  are decreasing with t, then the t  $\tilde{h}_i(s)ds + \mu_i \sigma_i^2$ ,  $r_t^i \rho_i(t) + \mu_i \sigma_i^2$  and  $\overline{\rho}_i$ t  $\begin{array}{lll} \textit{for $R_t^i$} & \frac{1}{t} \int_0^t \rho_i(s) ds + \mu_i & \sigma_i^2, \, r_t^i & \rho_i(t) + \mu_i & \sigma_i^2 \, \textit{and $\overline{\rho}_i$} & \left( \int_0^\infty \exp\left(-\int_0^t \rho_i(s) ds + \mu_i^2 \right) ds \right) \end{array}$ 

discount rates  $R_t$  and  $r_t$  are also decreasing with t and we have

$$
\lim_{t \to \infty} R_t \quad \lim_{t \to \infty} r_t \quad \inf_i \inf_t r_t^i \quad \inf_i \left( \mu_i \quad \sigma_i^2 + \lim_{t \to \infty} \rho_i(t) \right).
$$

## 5 Conclusion

In this paper, we propose an equilibrium approach to aggregate the discount rates proposed by experts into a consensus discount rate. We emphasize that our approach enables to deal with consumption discount rates and not only with utility discount rates (pure time preference rates).

We start with the recognition that divergence among experts on what the discount rate should be is rooted in fundamental differences of opinion about inter-generational equity as well as about future growth of the quantity of available consumption. This enables us to translate the problem of aggregating experts discount rates into a problem of aggregating heterogeneous beliefs and time preference rates. We can then use the techniques of Jouini et al. (2008) in order to obtain the expression of the socially efficient discount rate. The equilibrium discount rate is a weighted average of the experts proposed discount rates, in which more impatient experts are more heavily weighted; the equilibrium discount rate is decreasing and converges to the lowest expert discount rate, which does not necessarily correspond to the discount rate of the most 'patient' expert.

We show that the equilibrium discount rate is higher than Weitzman  $(1998)$ 's certainty equivalent discount rate for all horizon. More divergence of opinion about future growth rates among experts (in the form of second stochastic dominated shifts) leads to lower discount rates for all horizons.

More doubt (larger condence intervals) as well as more pessimism (in the form of first stochastic or monotone likelihood ratio dominated shifts) in experts' forecasts also leads to lower discount rates.

We calibrate the model on Weitzman  $(2001)$ 's data. We show that the very wide spread of opinion on discount rates makes the effective equilibrium discount rate decline significantly over time from 5 per cent per annum for Immediate Future to 0 per cent per annum for Far-Distant Future.

### Appendix

#### Derivation of the extended Ramsey equation

At the equilibrium, the date  $t$  state price density  $q_t$  is given by

$$
q_t = \exp(-\rho t)u'(e_t)
$$

and the discount rate is given by

$$
R = -\frac{1}{t} \ln E\left[q_t\right] - \rho - \frac{1}{t} \ln E\left[e_t^{-\eta}\right].
$$

 $\left(\mu - \frac{1}{2}\sigma^2\right)t$  and  $\sigma^2 n^2 t$ . We then have  $\ln E\left[c - \frac{1}{\eta}\right]$ 2  $\left[2\right]$  t and  $\sigma^2 n^2 t$ . We then have  $\ln |E| e^{-\frac{1}{n}}$  t(nu  $\frac{1}{2}$ 2  $\eta \left( \mu - \frac{1}{2} \sigma^2 \right) t$  and  $\sigma^2 \eta^2 t$ . We then have  $\ln E \left[ c^{-\frac{1}{\eta}} \right] = t (\eta \mu - \frac{1}{2} \eta (1 + \eta) \sigma^2)$  $\eta$ The random variable  $e_t$ <sup> $\eta$ </sup> follows a log normal distribution with parameters 1 and

$$
R \quad \rho + \eta \mu \quad \frac{1}{2} \eta \left( 1 + \eta \right) \sigma^2.
$$

#### Proof of Equation 1 and of Proposition 1

1  $i_t$  the consumption of group i. We let  $M^i \equiv \frac{f_i}{f}$  $\leq$ ∞  $\int_{0}^{\infty} E^{P} [a_{i} u_{i}^{n}] dt < m_{i} \int_{0}^{\infty}$  $i_t$   $\longrightarrow$   $N$   $r^i$  $\frac{w_i \rho_i}{\frac{N}{j-1}w_j \rho_j}$  $\sum_{i=1}^{N} \gamma_i \exp^{-R^i t}$   $\sum_{i=1}^{N}$  $\overline{\sum}$ R  $\int_{0}^{\infty} E^{P} [a_{t} u^{i}] dt < w_{i}$ We first prove that  $A_t = \sum_{i=1}^{N} \gamma_i \exp \frac{R^i t}{\sum_{i=1}^{N} \gamma_i \exp \frac{r^{i} t}{\sum_{i=1$  $0 \quad D \quad [4ty_t] \, ut \ \le \ w_t \, y_0$  $\frac{1}{w_i \rho_i}$ . Let us denote by  $q_t$ P) and by  $y_t^i$  the consumption of group *i*. We let  $M^i \equiv \frac{f_i}{f}(e_t)$ gregate utility  $\int_0^\infty \exp(-\rho_i t) E\left[M_t^i \log y_t^i\right] dt \leq w_i \int_0^\infty E^P\left[q_t e_t\right] dt$ . This lea  $A_t = \sum_{i=1}^N \gamma_i \exp^{-R^i t} = \sum_{i=1}^N \gamma_i \exp^{-r^i t}$ , with  $\gamma$  $\exp(-\rho_i t) E\left[ M_t^i \log y_t^i \right]$  $[q_{t} y_{t}^{i}] dt \leq w_{i} \int_{0}^{\infty} E^{P} [q_{t} e_{t}] dt$ . Let us denote by  $q_t$  the date  $t$ i  $\rho_i t) E\left[M_t^i \log y_t^i\right] dt$  $E^P\left[q_ty_t^i\right]dt \leq w_i\int_0^\infty E^P\left[q_te_t\right]dt.$ We first prove that  $A_t = \sum_{i=1}^N \gamma_i \exp^{-R^i t} = \sum_{i=1}^N \gamma_i \exp^{-r^i t}$ , with Let us denote by  $q_t$  the date t state-price density (with respect to P) and by  $y_t^i$  the consumption of group *i*. We let  $M^i \equiv \frac{f_i}{f}(e_t)$  denote the density of agenti's belief with respect to the true probability. Each group maximizes its aggregate utility  $\int_0^\infty \exp(-\rho_i t) E\left[M_t^i \log y_t^i\right] dt$  under its budget constraint  $\int_0^\infty E^P [q_t y_t^i] dt \leq w_t \int_0^\infty E^P [q_t e_t] dt$ . This leads to the following Euler conditions

$$
\frac{1}{\lambda_i} \exp(-\rho_i t) M_t^i \frac{1}{y_t^i} \quad q_t \quad \text{for all } i
$$

for some positive Lagrange multipliers  $(\lambda_i)$ 

We have then

Г

$$
\frac{1}{\lambda_i} \exp(-\rho_i t) M_t^i \frac{1}{q_t} - y_t^i
$$

and summing all these equations leads to

$$
q_t \sum_{i=1}^N \frac{1}{\lambda_i} \exp(-\rho_i t) M_t^i \frac{1}{e_t}.
$$

 $i_f$   $R^i$ t Now, in our setting,  $\exp^{-rit}$   $\exp^{-R^it}$   $E\left[\exp(-\rho_i t)M_t^i\frac{1}{e_t}\right]$ , hence

$$
A_t
$$
  $E[q_t]$   $\sum_{i=1}^N \frac{1}{\lambda_i} \exp r^{it}$   $\sum_{i=1}^N \frac{1}{\lambda_i} \exp r^{it}$ .

i 1 It remains to determine the equilibrium weights  $\frac{1}{\lambda_i}$ . From the Euler and budget conditions we have

$$
\int_0^\infty E^P \left[ q_t y_t^i \right] dt \quad \frac{1}{\lambda_i \rho_i} \quad w_i \int_0^\infty E^P \left[ q_t e_t \right] dt
$$

which leads to

$$
\frac{1}{\lambda_i} \quad \frac{\rho_i w_i}{\sum_{j=1}^N \rho_j w_j}
$$

.

We easily deduce Equations  $(1)$ ,  $(2)$  as well as Equation  $(3)$ .

 $\equiv \sum_{i=1}^{N} \frac{w_i \rho_i \exp\left(-r^i\right)}{\sum_{j=1}^{N} w_j \rho_j \exp\left(-r^i\right)}$ 2 N  $\frac{1}{2}\sum_{j=1}^N w_j \rho_j \exp(-r^j)$ exp r is concerned, we have  $r_t \equiv \sum_{i=1}^{N} \frac{w_i \rho_i \exp(-r^i t)}{\sum_{i=1}^{N} w_i \rho_i \exp(-r^i t)} r^i$ ,  $w_i \rho_i \exp(-r^i t)$  $w_j \rho_j \exp(-r^j t)$ As far as the monotony of r is concerned, we have  $r_t \equiv \sum_{i=1}^{N} \frac{w_i \rho_i \exp(-r_i t)}{\sum_{i=1}^{N} r_i} r^i$ 

1 1 2 1  $\begin{bmatrix} \frac{t}{r} \end{bmatrix} \quad E^{P_{\rho\,\exp}}\left[r\right]^2 \quad E^{P_{\rho\,\exp}}\left[r^2\right] \leq$  $\sum$  $\frac{\sum_{i=1}^N w_i \rho_i \exp(-r^i t) r^i\big)^2}{\sum_{i=1}^N w_i \rho_i \exp(-r^i t)\big)^2} \quad \quad \sum_{i=1}^N \frac{1}{\sum_{i=1}^N}$  $dr_t$  $\sum\limits_{i=1}^N w_i \rho_i \exp\left(-r^i t\right) r^i\Big]$  $\frac{N}{i-1}w_i\rho_i \exp(-r^i$  $\partial_i \exp(-r^i)$ N  $\int_{j=1}^{N} w_j \rho_j \exp(-r^j)$ exp  $\exp(-r^i t)\Big)^2$   $\qquad 2i$  1 exp  $\exp(-r^{j}t)$  $\frac{\left(\sum_{i=1}^{N} w_i \rho_i \exp\left(-r^i t\right) r^i\right)^2}{\left(\sum_{i=1}^{N} w_i \rho_i \exp\left(-r^i t\right)\right)^2} = \sum_{i=1}^{N} \frac{w_i \rho_i \exp\left(-r^i t\right)}{\sum_{i=1}^{N} w_i \exp\left(-r^i t\right)} \left(r^i\right)^2.$  $\frac{1}{(r_i)^2}$  and  $\frac{1}{(r_i)^2}$  are  $\frac{1$ P  $w_i \rho_i \exp\left(-r^i t\right)$ . We have  $\frac{dr_t}{dt} = E^{P_{\rho \exp}}[r]^2 = E^{P_{\rho \exp}}[r^2] \leq 0$ . discount rate  $r_t$  decreases then with  $t$ .  $\left(\sum_{i=1}^{N} w_i \rho_i \exp(-r^i t)\right)$  $\frac{w_i \rho_i \exp(-r^i t) r^i}{\left(1-\frac{1}{2}\right)^2} = \sum_{i=1}^N \frac{w_i \rho_i \exp(-r^i t)}{\sum_{i=1}^N \exp(-r^i t)} \left(r^i\right)^2$ dt  $w_i \rho_i \exp(-r^i t)$ N i  $w_i \rho_i \exp(-r^i t)$  $w_j \rho_j \exp(-r^j t)$ then  $\frac{dr_t}{dt} = \frac{(\sum_{i=1}^n w_i \rho_i \exp(-r \nu) r)}{(\sum_{i=1}^N w_i \sqrt{r})^2} = \sum_{i=1}^N \frac{w_i \rho_i \exp(-r \nu)}{(\sum_{i=1}^N (r^i))^2}$ . Let us con- $\rho$  $_i \rho_i \exp(-r^i t)$ . We have  $\frac{dr}{dt}$ dt  $P_{\rho \text{ exp}}$   $\lceil r \rceil^2$   $\qquad$   $\qquad$ sider  $P_{\rho \text{exp}}$  the probability measure whose weights are proportional to by We have  $\frac{dr_t}{dt}$   $E^{P_{\rho \exp}}[r]^2$   $E^{P_{\rho \exp}}[r^2] \leq 0$ . The marginal

concerned, let  $r^i \equiv \inf_i r^i$  and let j be such that  $r^j / r^{i^*}$ , then the relative \* weight of  $r^j$  in Equation (2) converges to zero and  $r_t \rightarrow_{t \rightarrow \infty} r^{i^*}$ . As far as the asymptotic behavior of the marginal discount rate  $r$  is

#### Proof of Proposition 2

1. According to Proposition 1, we have

$$
R_t \equiv \frac{1}{t} \ln A_t
$$

where  $A_t$  is an arithmetic average of the exp  $R^i t$ . Since the arithmetic average is larger than the geometric average, we have

$$
\sum_{i=1}^{N} \frac{w_i \rho_i}{\sum_{j=1}^{N} w_j \rho_j} \exp\left(-R^i t\right) \ge \exp\sum_{i=1}^{N} \frac{w_i \rho_i}{\sum_{j=1}^{N} w_j \rho_j} R^i t.
$$

Hence,

$$
R_t \le \sum_{i=1}^N \frac{w_i \rho_i}{\sum_{j=1}^N w_j \rho_j} R^i.
$$

We have

$$
r_t \equiv \sum_{i=1}^{N} \frac{w_i \rho_i \exp(-r^i t)}{\sum_{j=1}^{N} w_j \rho_j \exp(-r^j t)} r^i
$$

$$
\frac{E^{P_\rho}[\exp(-rt) r]}{E^{P_\rho}[\exp(-rt)]}
$$

 $\sum_{j=1}^N$  $\leq$  $\frac{w_i \rho_i}{\frac{N}{j-1} w_j \rho_j}$  $\lvert \rho \rvert$  exp  $\lvert \rvert$   $r t$   $\lvert r^i \rvert \leq F_1^P \rho$   $\lvert r \rvert$   $F_2^P \rho$  $P_{\rho}$  has weights  $\frac{w_i \rho_i}{\sum_{i=1}^{N}}$ . Since exp $(r^i t)$  decreases with  $r^i$ ,  $E^{P_{\rho}}\left[\exp\left(-rt\right)r^{i}\right]\leq E^{P_{\rho}}\left[r\right]E^{P_{\rho}}\left[\exp\left(-rt\right)\right].$  $\exp{(-r^i t)}$  $[\exp(-rt) r^i] \leq E^{P_\rho}[r] E^{P_\rho}[\exp(-rt)]$  $\mathcal{P}_{\rho}$  has weights  $\frac{w_i \rho_i}{\sum_{i=1}^{N} w_i}$  $w_i \rho$  $\left\{i_t\right\}$  decreases with  $r^i$  $P_{\rho}$  [exp(r)  $r^{i}$   $\langle E^{P_{\rho}}$  [r]  $E^{P_{\rho}}$ where  $P_{\rho}$  has weights  $\frac{w_i \rho_i}{\sqrt{N}}$ . Since  $\exp(-r^i t)$  decreases with  $r^i$ , we have Hence

$$
r_t \leq E^{P_\rho}[r] \quad \sum_{i=1}^N \frac{w_i \rho_i}{\sum_{j=1}^N w_j \rho_j} r^i.
$$

and  $b_i \equiv \mu_i \quad \sigma_i^2$  are independent, we have 2. Let us denote by  $P_w$  the probability measure with weights  $w_i$ . Since  $\rho_i$ 

$$
\exp(-R_t t) \qquad \frac{E^{P_w}[\rho \exp(-\rho t) \exp(-bt)]}{E^{P_w}[\rho]}
$$
\n
$$
\frac{E^{P_w}[\rho \exp(-\rho t)] E^{P_w}[\exp(-bt)]}{E^{P_w}[\rho]}.
$$

Now, since  $\rho_i$  and exp (  $\rho_i t$ ) are anticomonotonic, we have

$$
E^{P_w}[\rho \exp(-\rho t)] \le E^{P_w}[\rho] E^{P_w}[\exp(-\rho t)],
$$

which gives

$$
\exp \quad R_t t \geq E^{P_w} [\exp (-\rho t)] E^{P_w} [\exp (-bt)],
$$
  

$$
\geq E^{P_w} [\exp (-rt)].
$$

3. We have

$$
r_t \quad \frac{E^{P_{\exp}}[\rho^2] + E^{P_{\exp}}[\rho b]}{E^{P_{\exp}}[\rho]}.
$$

where  $P_{\text{exp}}$  denotes the probability measure whose weights are proportional to  $w_i \exp(-r^i t)$ . We have then

$$
r_{t} \geq \frac{E^{P_{\exp}}[\rho]^{2} + E^{P_{\exp}}[\rho b]}{E^{P_{\exp}}[\rho]},
$$
  
\n
$$
\geq E^{P_{w}}[\rho \exp(-\rho t)] \frac{E^{P_{w}}[\rho \exp(-\rho t)] E^{P_{w}}[\exp(-bt)] + E^{P_{w}}[\exp(-bt)] E^{P_{w}}[\exp(-\rho t)]}{E^{P_{w}}[\exp(-\rho t)] E^{P_{w}}[\rho \exp(-\rho t)]},
$$
  
\n
$$
\geq \frac{E^{P_{w}}[(\rho + b) \exp(-(\rho + b) t)]}{E^{P_{w}}[\exp(-bt)]},
$$
  
\n
$$
\geq \sum_{i=1}^{N} \frac{w_{i} \exp(-r^{i}t)}{\sum_{j=1}^{N} w_{j} \exp(-r^{j}t)} r^{i}.
$$

#### Proof of Proposition 3

П

2  $\sim \gamma(\alpha_1, \beta_1)$  and  $b_i \sim \gamma(\alpha_2, \beta_2)$  $i_i$  and beliefs  $\theta_i$   $\mu_i$   $\sigma_i$  $i \sim \gamma(\alpha_1, \beta_1)$  and  $\theta_i$  $\rho_i$  and beliefs  $b_i$   $\mu_i$   $\sigma$  $\rho_i \sim \gamma(\alpha_1, \beta_1)$  and  $b_i \sim \gamma(\alpha_2, \beta_2)$ , If pure time preference rates  $\rho_i$  and beliefs  $b_i - \mu_i - \sigma_i^2$  are independent and are distributed as follows  $\rho_i \sim \gamma(\alpha_1, \beta_1)$  and  $b_i \sim \gamma(\alpha_2, \beta_2)$ , then

$$
A_{t} \frac{\beta_{2}^{\alpha_{2}}}{\Gamma(\alpha_{2})} \frac{\beta_{1}^{\alpha_{1}}}{\Gamma(\alpha_{1})} \frac{\int_{0}^{\infty} \int_{0}^{\infty} \rho \exp\left(-(\rho+b) t\right) \rho^{\alpha_{1}-1} \exp\left(-\beta_{1} \rho\right) b^{\alpha_{2}-1} \exp\left(-\beta_{2} b\right) d\rho db}{\frac{\beta_{2}^{\alpha_{2}}}{\Gamma(\alpha_{1})} \int_{0}^{\infty} \rho \rho^{\alpha_{1}-1} \exp\left(-\beta_{1} \rho\right) d\rho}
$$
\n
$$
\frac{\beta_{2}^{\alpha_{2}}}{\Gamma(\alpha_{2})} \frac{\left(\int_{0}^{\infty} \exp\left(-\rho\left(\beta_{1}+t\right)\right) \rho^{\alpha_{1}} d\rho\right) \left(\int_{0}^{\infty} \exp\left(-b\left(\beta_{2}+t\right)\right) b^{\alpha_{2}-1} db\right)}{\int_{0}^{\infty} \rho^{\alpha_{1}} \exp\left(-\beta_{1} \rho\right) d\rho},
$$
\n
$$
\left(\frac{\beta_{1}}{\beta_{1}+t}\right)^{1+\alpha_{1}} \left(\frac{\beta_{2}}{\beta_{2}+t}\right)^{\alpha_{2}}.
$$

Proof of Proposition 4 The results on the expression of  $R$  and  $r$  are then easily derived.

1. Let us assume that all the agents have the same  $\rho_i$ , we have then

$$
R_t \equiv \frac{1}{t} \ln E^{P_w} [\exp \ Rt]
$$

 $E^{P_w}$  [exp Rt] and increases  $R_t$ . function  $R \to \exp(Rt)$  is decreasing (and convex) and, by definition, a where  $P_w$  is defined as in the proof of Proposition. For a given t, the FSD (resp. SSD) shift in the distribution of  $(R<sup>i</sup>)$  decreases the value of

2. We still assume that all the agents have the same  $\rho_i$ , we have then

$$
r_t = \frac{E^{P_w}[r \exp(-rt)]}{E^{P_w}[\exp(-rt)]}.
$$

w  $\overline{W}$ <br>
We have the  $E^{P_w^2}$  $P^2_w$  $P_w^1$  $P_{w}^{1}$  $\pmb Q$  $\overline{Q}$  $\leq$  $\rightarrow$  $\rightarrow$ 2 1 2 2 1 1 exp  $\frac{E^{\text{Qexp}}[\phi r]}{E^{\text{Qexp}}[\phi]}$  where  $Q_{\text{exp}}$  is defined by a density with respect to  $P_w^1$ <sup>1</sup> and  $P^2$  two distributions such that  $P^2 \succeq_{M,D} P^1$  $[r \exp \tau t]$  $[\exp(-rt)]$  $[\phi r \exp \tau t]$  $[\phi \exp(-rt)]$  $w_w$  and  $F_w$ , two distributions such that  $F_w \subseteq MLR$   $F_w$ <br> $w \nightharpoonup \frac{dP_w^2}{dr}$  is ponder posing in  $r$  (in other words i  $dP$ i i are comonotonic) We have then  $E^{P_w^x}[r \exp \tau t]$  $E^{P\tilde{\bm{w}}}\left[\exp(-rt)\right]$  $E^{P_w^+}[\phi r \exp \tau t$  $E^{P_{\boldsymbol{w}}}[\phi\exp(-rt)]$  $\frac{E^{\text{Vexp}}[\phi r]}{E^{\text{Qexp}}[\phi]}$  where  $Q_{\text{exp}}$  is defined by a density with respect to  $P_w^1$  equal (up to  $P_w^1$  and  $P_w^2$ , two distributions such that  $P_w^2 \succeq_{MLR} P_w^1$ .  $\phi$   $\frac{dP_{\psi}^{x}}{dP^{1}}$  is nondecreasing in r (in other words  $i \to \phi$  $i \rightarrow r^i$ a constant) to  $\exp(-rt)$ . Since  $\phi$  is nondecreasing in r, we have Let us consider  $P_w^1$  and  $P_w^2$ , two distributions such that  $P_w^2 \succeq_{MLR} P_w^1$ . By definition, the density  $\phi = \frac{dP_w}{dP^1}$  is nondecreasing in r (in other words and  $i \rightarrow r^i$  are comonotonic). We have then,

$$
E^{Q_{\exp}}\left[\phi r\right] \geq E^{Q_{\exp}}\left[\phi\right]E^{Q_{\exp}}\left[r\right],
$$

hence

$$
\frac{E^{P_w^2}[r \exp \tau t]}{E^{P_w^2}[\exp(\tau t)]} \geq E^{Q_{\exp}}[r],
$$
  

$$
\geq \frac{E^{P_w^1}[r \exp \tau t]}{E^{P_w^1}[\exp \tau t]}.
$$

3. If we now assume that all the agents have the same belief, we have

$$
R_t \equiv \frac{1}{t} \ln \frac{E^{P_w} [\rho \exp \rho t]}{E^{P_w} [\rho]}.
$$

.

2 2 1 1 2 1 er  $P_w^v$  and  $P_w^v$ , two distributions such that  $P_w^v \succeq$ <br> $P_w^v|_{\rho \exp \phi t}$   $E^{P_w^1|_{\phi \rho \exp \phi t}}$   $E^{Q_\rho|_{\phi \exp \phi t}}$   $E^{Q_\rho|_{\phi \exp \phi t}}$  $P^2_w$  $P_w^1$  $P_{w}^{1}$  $Q_{\boldsymbol{\rho}}$  $\frac{\rho \exp \rho \mu_1}{Q_{\rho}[\phi]}$  where  $\phi$   $\frac{dF_w}{dP^1}$  $\bar{w}$ <sup>1</sup> and  $P^2$  two distributions such that  $P^2 \succ_{M,D} P^1$  $[\rho \exp \rho t]$  $[\rho]$  $[\phi \rho \exp \theta t]$  $[\phi \rho]$  $[\phi \exp \theta t]$  $\lbrack \phi \rbrack$ 1 to  $\rho$ . Since  $\phi$  is nondecreasing in r and then nonincreasing in exp  $\rho t$ , we  $w$  and  $F_w$ , two distributions such that  $F_w \subseteq MLR$   $F_w$  $E^{P^{\boldsymbol{\pi}}_w}[\rho\exp\ \rho t]$  $E^{P^{\boldsymbol{\pi}}_w}[\rho]$  $E^{P_{\boldsymbol{w}}}[\phi \rho \exp \varphi t]$  $E^{P_w^+}[\phi\rho$  $E^{Q\rho}[\phi \exp \theta \rho t]$  $E^{\bm{Q} \rho}[\phi]$  $dP$  $dP$  $_{\rho}$  is defined by a defisity with respect to  $r_{w}$  $P_w^1$  and  $P_w^2$ , two distributions such that  $P_w^2 \succeq_{MLR} P_w^1$ .  $\phi$  $Q_{\rho}$  is defined by a density with respect to F Let us consider  $P_w^1$  and  $P_w^2$ , two distributions such that  $P_w^2 \succeq_{MLR} P_w^1$ . We have then,  $\frac{E^{\mu}w[\rho\exp-\rho t]}{rP^2}$   $\frac{E^{\mu}w[\rho\rho\exp-\rho t]}{rP^2}$   $\frac{E^{\mu}(\rho\exp-\rho t)}{F^2Q\rho[A]}$  where  $\phi$   $\frac{dP_w^2}{dP^1}$  and where  $Q_{\rho}$  is defined by a density with respect to  $P_w^1$  equal (up to a constant) have

$$
E^{Q_{\rho}}\left[\phi \exp \quad \rho t\right] \leq E^{Q_{\rho}}\left[\phi\right] E^{Q_{\rho}}\left[\exp \quad \rho t\right],
$$

hence

$$
\frac{E^{P_w^2}[\rho \exp \rho t]}{E^{P_w^2}[\rho]} \leq E^{Q_\rho}[\exp \rho t],
$$
  

$$
\leq \frac{E^{P_w^1}[\rho \exp \rho t]}{E^{P_w^1}[\rho]}.
$$

#### Proof of Proposition 5

∞  $\int_{0}^{\infty} E^{P} [a_{i} u_{i}^{i}] dt < w_{i} \int_{0}^{\infty}$  $\int_{0}^{\infty} \exp(-\rho t) E^{Q_t^i} \left[ \frac{1}{\epsilon} \right]$  $\int_0^\infty E^P [q_t y_t^i] dt \leq w_i$   $\int$  $\sum_{i=0}^{\infty} \exp(-\rho_i t) E^{Q_t^i} \left[ \frac{1}{y_t^i} \right]$  $0 \quad D \quad [4t \mathcal{Y}_t] \, u \geq u \mathcal{Y}_t$  $\exp(-\rho_i t)$  $[q_t y_t^i] dt \leq w_t \int_0^\infty E^P [q_t e_t] dt$ Let  $M_t^i$  denote the density of  $Q_t^i$  with respect to a given probability  $P$ equivalent to all the probability measures  $Q_t^i$ . Let us denote by  $q_t$  the date  $t$ state-price density (with respect to  $P$ ) and by  $y_t^i$  the consumption of group  $_i(t)E^Q$  $\overline{y}$  $\frac{d}{dt} P \left[ q_t y_t^i \right] dt \leq w_i \int_0^\infty E^P \left[ q_t e_t \right] dt$ *i*. Each group maximizes its aggregate utility  $\int_0^\infty \exp(-\rho_i t) E^{Q_t^i} \left| \frac{1}{n^i} \right| dt$  $E^P\left[q_ty_t^i\right]dt \leq w_i\int_0^\infty E^P\left[q_te_t\right]dt.$ Each group maximizes its aggregate utility  $\int_0^\infty \exp(-\rho_i t) E^{Q_t^i} \left| \frac{1}{n^i} \right| dt$  under its budget constraint  $\int_0^\infty E^P [q_t y_t^i] dt \leq w_i \int_0^\infty E^P [q_t e_t] dt$ . This leads to the following Euler condition

$$
\frac{1}{\lambda_i} \exp(-\rho_i t) M_t^i \frac{1}{y_t^i} \quad q_t.
$$

We have then

$$
\frac{1}{\lambda_i} \exp(-\rho_i t) M_t^i \frac{1}{q_t} - y_t^i
$$

and summing all these equations leads to

$$
q_t \sum_{i=1}^N \frac{1}{\lambda_i} \exp(-\rho_i t) M_t^i \frac{1}{e_t}.
$$

Now in an economy made of group  $i$  only, we would have

$$
\exp(-\rho_i t) M_t^i \frac{1}{e_t} - q_t^i
$$

and

$$
r_t^i \qquad \frac{1}{t} \ln E\left[q_t^i\right].
$$

 $q_0$  1 and  $\sum_{i=1}^{N} \frac{1}{\lambda_i}$  1 which leads to If all prices are expressed in terms of today's consumption units, we have

$$
q_t \quad \sum_{i=1}^N \frac{1}{\lambda_i} q_t^i
$$

hence

$$
A_t \quad \sum_{i=1}^N \frac{1}{\lambda_i} A_t^i.
$$

i It remains to determine the equilibrium weights  $\frac{1}{\lambda_i}$ . From the Euler conditions and budget conditions we have

$$
\int_0^\infty E^P \left[ q_t y_t^i \right] dt \quad \frac{1}{\lambda_i \rho_i} \quad w_i \int_0^\infty E^P \left[ q_t e_t \right] dt
$$

which leads to

$$
\frac{1}{\lambda_i} \quad \frac{\rho_i w_i}{\sum_{j=1}^N \rho_j w_j}
$$

1  $q_t$   $\sum_{i=1}^N \frac{\rho_i w_i}{\sum_{j=1}^N \rho_j w_j} q_t^i$ . Since  $A_t$   $E[q_t]$ ,  $\rho_i w$  $\rho_i w$ and  $q_t = \sum_{i=1}^{N} \frac{\rho_i w_i}{\sum_{i=1}^{N} \rho_i w_i} q_t^i$ . Since  $A_t = E[q_t]$ , we have

$$
A_t \quad \sum_{i=1}^N \frac{\rho_i w_i}{\sum_{j=1}^N \rho_j w_j} A_t^i,
$$

hence Equation (7).

Proof of Proposition 6 It is easy to see that the formulas in the proof of Proposition 5 above have to be adapted as follows

$$
q_t \qquad \frac{1}{\lambda_i} \exp\left(-\int_0^t \rho_i(s)ds\right) M_t^i \frac{1}{y_t^i}
$$

$$
\int_0^\infty E^P \left[q_t y_t^i\right] dt \qquad \int_0^\infty \frac{1}{\lambda_i} \exp\left(-\int_0^t \rho_i(s)ds\right) dt
$$

The same steps as above lead to

$$
A_t \sum_{i=1}^N \frac{\overline{\rho}_i w_i}{\sum_{j=1}^N \overline{\rho}_j w_j} A_t^i
$$
  
with  $\overline{\rho}_i \left( \int_0^\infty \exp\left(-\int_0^t \rho_i(s)ds\right) dt \right)^{-1}$ .

Figure 1: We calibrate a model with two independent gamma distributions (tastes and beliefs) on Weitzman (2001)'s data. We assume that the two distributions are homothetic (the first one is obtained from the second one through a change of variable  $x \to \lambda x$  where  $\lambda$ is a given parameter) and we calibrate the model in order to fit the mean and the variance of the empirical distribution. We have then a family of stastical models that contains Weitzman (2001)'s statistical model (it corresponds to  $\lambda = 1$ ) and we maximize the log-likelihood with respect to the parameter  $\lambda$  to choose the best calibration. We obtain  $\lambda = 0.4116$ .

Figure 2: This figure represents the distribution of the individual discount rates for the value  $\lambda = 0.4116$  that maximizes the log-likelihood (upper curve) as well as the empirical distribution and Weitzman (2001)'s distribution (lower curve). Our distribution corresponds to the sum of two independent gamma distributions with parameters  $(\alpha_1, \beta_1)$  and  $(\alpha_2, \beta_2)$  given by  $(\alpha_1, \beta_1, \alpha_2, \beta_2) = (1.04, 89.45, 1.04, 36.82)$ . These parameters correspond to mean and variance levels given by  $(m_1, v_1^2, m_2, v_2^2) = (1.16 \times 10^{-2}, 1.30 \times 10^{-4}, 2.83 \times 10^{-2}, 7.69 \times 10^{-4}).$ Weitzman's distribution corresponds to a gamma distribution with parameters  $(1.78, 44.44)$ . All represented distributions have the same mean and variance levels  $(m, v^2) = (4 \times 10^{-2}, 9 \times$  $10^{-4}$ ).

Figure 3: This figure represents the marginal discount rate curve  $r_t$  $\sum_{i=1}^N$  $w_i \rho_i \exp(-r^i t)$  $\frac{w_i \rho_i \exp(-r^{\nu} t)}{\sum_{j=1}^N w_j \rho_j \exp(-r^j t)} r^i \;\;=\;\; \frac{\alpha_1+1}{\beta_1+t} \;+\; \frac{\alpha_2}{\beta_2+1}$  $\frac{\alpha_2}{\beta_2+t}$  obtained through our calibration (upper curve) and compares it to the discount rate curve  $r_t = \frac{\alpha}{\beta + 1}$  $\frac{\alpha}{\beta+t}$  of Weitzman (2001) (lower curve). The intermediate curve represents, with our calibration, the unweighted average  $\sum_{i=1}^{N}$  $w_i \exp\left(-r^i t\right)$  $\frac{w_i\exp(-r\cdot t)}{\sum_{j=1}^N w_j\exp(-r^jt)}r^i\,=\,\frac{\alpha_1}{\beta_1+t}\,+\,\frac{\alpha_2}{\beta_2+t}$  $\frac{\alpha_2}{\beta_2+t}$ . It is clear that the difference between our discount rate curve and Weitzman (2001)'s curve mainly results from the fact that, contrarily to the certainty equivalent approach, more impatient experts are more heavily weighted in the equilibrium approach.

Time period	Name	Numerical	Approx.	Weitzman's num. value	Weitzman's appr. rate
		value	rate		
Within years 1	Immediate	4.99%	$5\%$	3.89%	$4\%$
to 5 hence	Future				
Within years 6	Near	4.23%	$4\%$	$3.22\%$	$3\%$
to 25 hence	Future				
Within years 26	Medium	2.82%	$3\%$	$2.00\%$	$2\%$
to 75 hence	Future				
Within years 76	Distant	1.50%	$1.5\%$	$0.97\%$	$1\%$
to 300 hence	Future				
Within years	Far-Distant	$0.16\%$	$0\%$	$0.08\%$	$0\%$
more than 300 hence	Future				

Table 1 - Approximate recommended sliding-scale discount rates

This table compares for different time periods the recommended discount rates that result from our approach and those resulting from Weitzman (2001)'s approach. These rates are computed recursively. For the first period, we compute the rate that, if applied continuously from date 0 to the middle of the period would lead to the discount rate for that maturity. For next periods, we compute the rate that, if applied continuously from the beginning of the period to the middle of the period and compounded with the rates already computed for previous periods would lead to the discount rate for that maturity. The exact as well as approximate (recommended) results are then provided for both approaches.
