## **ACKNOWLEDGEMENTS**

Stefanie Jung was supported by the first Leibniz-WissenschaftsCampus Tuebingen "Bildung und Informationsumwelten" as well as by the German Research Foundation (DFG) providing funding to Elise Klein (KL 2788/2-1). Elise Klein was supported by the Margarete von-Wrangell Fellowship (European Social Fund and the Ministry of Science, Research and the Arts Baden-Württemberg). We thank the participating children, their parents and institutions who made this work possible. We also thank all research assistants for their assistance with data collection.

**ABSTRACT:**

Changes in number line estimation (NLE) performance are frequently used as an indicator for the development of the number magnitude representation. For this purpose, two different task versions have been applied: a traditional bounded and a relatively new unbounded NLE task. Previous studies mainly assessed primary school children or adults showing that these tasks differ in terms of i) estimation accuracy and solution strategies employed as well as ii) with respect to their relation to other basic numerical/arithmetic skills. So far, data from secondary school children are scarce for bounded NLE, and even no data is available for unbounded NLE. Thus, we assessed bounded and unbounded NLE in grade levels 5 to 7 to evaluate a) developmental as well as strategic influences, and b) the relation of bounded and unbounded NLE performance with basic arithmetic skills. Our results show that children employed the use of different solution strategies for bounded (i.e., proportion-judgement) and unbounded (i.e., magnitude-estimation based) NLE. Moreover, only for bounded NLE estimation accuracy increased with age. Furthermore, estimation performance for bounded but not unbounded NLE was strongly associated with basic arithmetic (addition, subtraction, multiplication, and division). Our findings indicate that the differential results for bounded and unbounded NLE obtained in primary school children seem to generalize to older secondary school children. Presented results substantially contribute to the knowledge about the (consecutive) development of skills pertaining to bounded and unbounded number line estimation.

1       **INTRODUCTION:**  
2  
3

4       Number line estimation (NLE) refers to the ability to locate numbers on a physical line  
5  
6       according to their magnitude. NLE performance is a widely used indicator of basic numerical  
7  
8       skills in studies evaluating the development of numerical skills through childhood. Traditionally,  
9  
10       NLE refers to estimation performance on a *bounded* number line estimation task. In bounded  
11  
12       number line estimation, start and endpoint of a specific number range (e.g., 0 to 100) is typically  
13  
14       specified by a minimum value indicated at the left end of the number line and a maximum  
15  
16       value at the right end of the line. Participants are required to estimate the spatial position of a  
17  
18       given number (e.g., Siegler and Opfer, 2003). Compared to that, *unbounded* NLE performance  
19  
20       has been assessed less frequently, but more and more recently (e.g., Cohen & Blanc-  
21  
22       Goldhammer, 2011; Link, Huber, Nuerk, & Moeller, 2014; Reinert, Hartmann, Huber, & Moeller,  
23  
24       2019). In the unbounded NLE task, the number line has no labelled endpoint, but a single unit  
25  
26       distance (e.g., 0-1) in addition to the start point. Starting from this unit distance, target numbers  
27  
28       have to be located upon the given line.  
29  
30  
31  
32  
33  
34  
35  
36

37  
38       Bounded and unbounded NLE tasks have been used as indicators to draw conclusions from  
39  
40       task performance onto the underlying magnitude representation and its development (e.g., for  
41  
42       bounded NLE: Berteletti, Lucangeli, Piazza, Dehaene, & Zorzi, 2010; Booth & Siegler, 2006,  
43  
44       2008; Ebersbach, Luwel, & Verschaffel, 2015; Siegler & Booth, 2004; Siegler & Opfer, 2003;  
45  
46       Thompson & Opfer, 2010; Young & Booth, 2015; e.g., for unbounded NLE: Cohen & Blanc-  
47  
48       Goldhammer, 2011; Link, Huber, et al., 2014). However, the two tasks were found to differ in  
49  
50       terms of i) the solution strategies employed (e.g., considering the usage of reference points [cf.  
51  
52       Cohen & Blanc-Goldhammer, 2011; Cohen & Sarnecka, 2014; Link, Huber, et al., 2014]) and ii)  
53  
54       their association with other basic numerical as well as arithmetic skills (for a meta-analysis see  
55  
56  
57  
58  
59  
60  
61  
62  
63  
64  
65

1 Schneider et al., 2018). More importantly, despite numerous studies relating primarily bounded  
2  
3 NLE to other basic numerical and arithmetic skills, the vast majority of these studies focused  
4  
5 either on young children from kindergarten to the end of primary school (e.g., Link, Nuerk, et  
6  
7 al., 2014; Moeller et al., 2009; Schneider et al., 2017; Zhu et al., 2017) or adults (Reinert, Huber,  
8  
9 Nuerk, & Moeller, 2017, 2015). So far, the age range in-between (i.e., secondary school children)  
10  
11 has largely been neglected for bounded NLE. For unbounded NLE, there is still no empirical  
12  
13 data at all from secondary school children. Crucially, consideration of relatively narrow age  
14  
15 ranges strongly limits general statements on the development of number representation.  
16  
17  
18  
19  
20  
21

22 In the current study, we aimed at addressing this gap by investigating bounded and  
23  
24 unbounded NLE in secondary school children<sup>1</sup> (i.e., 5<sup>th</sup> to 7<sup>th</sup> graders) to evaluate both a)  
25  
26 developmental changes in *estimation accuracy and strategy use* and b) the relation of bounded  
27  
28 and unbounded *number line estimation with basic arithmetic*.  
29  
30  
31

### 32 *Estimation accuracy and strategy use*

33  
34  
35  
36

37 Regarding bounded NLE, there are different views on the developmental changes of NLE  
38  
39 performance and its relationship to the underlying representation of number magnitude.  
40  
41 Generally, all views are based on the observation that children of different age groups perform  
42  
43 differently in the same number range: Younger children (i.e., preschoolers and first-graders)  
44  
45 were observed to systematically overestimate the spatial position of small numbers (i.e., placing  
46  
47 9 at about the location where 40 would go on a 0-100 scale; Moeller et al., 2009). In turn, they  
48  
49 localised larger numbers in a compressed way towards the upper bound of the scale (e.g.,  
50  
51 Siegler & Booth, 2004; Siegler & Opfer, 2003). Older children (e.g., second-graders), in contrast,  
52  
53  
54  
55  
56  
57  
58  
59  
60

---

61 <sup>1</sup> In the German school system, majority of secondary schools begins with the 5th grade.  
62  
63  
64  
65

1 did not show such a pattern and were observed to perform more accurately in the same  
2  
3  
4 number range (e.g., Siegler & Booth, 2004).  
5

6  
7 These estimation patterns have been discussed in various theoretical accounts (see  
8  
9 Dackermann et al., 2015, for a recent review). Most importantly, two competing accounts can  
10  
11 be differentiated: the log-to-linear shift account (e.g., Booth & Siegler, 2006; Siegler & Booth,  
12  
13 2004; Siegler & Opfer, 2003) and the proportion-judgement account (e.g., Barth & Paladino,  
14  
15 2011; Slusser, Santiago, & Barth, 2013).  
16  
17  
18  
19  
20

21 The log-to-linear shift account proposes a representational change from an initially logarithmic  
22  
23 layout, as indicated by overestimation of smaller numbers, to a more linear layout of estimation  
24  
25 patterns with increasing age and experience. Accordingly, a logarithmic function was found to  
26  
27 fit the observed estimation pattern best in younger children whereas a linear function reflected  
28  
29 the observed estimation patterns best in older children and adults (Booth & Siegler, 2006, 2008;  
30  
31 Siegler & Booth, 2004; Siegler & Opfer, 2003). The account assumes estimation patterns to  
32  
33 directly reflect the underlying magnitude representation (Siegler & Opfer, 2003). However, the  
34  
35 interpretation of a direct assessment of the magnitude representation is questioned in  
36  
37 alternative accounts that emphasize the importance of other numerical processes in addition  
38  
39 to the pure magnitude estimation. Ebersbach, Luwel, Frick, Onghena, and Verschaffel (2008),  
40  
41 for instance, mentioned the increasing familiarity of children with numbers (but see Thompson  
42  
43 & Opfer, 2010 for results contradicting the assumption that children's familiarity with numbers  
44  
45 predicts individual's mental representation of the number line), whereas Moeller et al., 2009  
46  
47 suggested to consider the understanding of the place-value system, which also affects NLE  
48  
49 performance.  
50  
51  
52  
53  
54  
55  
56  
57  
58  
59  
60  
61  
62  
63  
64  
65

1 The most prominent alternative account, the proportion-judgement account, postulates that  
2  
3 potential reference points (i.e., start and end point of the respective scale, but also quartiles  
4  
5 and midpoint, also referred to as [subjective] landmarks) are considered for estimation (e.g.,  
6  
7 Barth & Paladino, 2011; Siegler & Opfer, 2003; Slusser et al., 2013). The use of reference points  
8  
9 is supposed to increase with age and to enhance estimation accuracy (e.g., Slusser et al., 2013;  
10  
11 see also Schneider et al., 2008, for eye-fixation data.). Evidence for the account comes from  
12  
13 children's estimation patterns: while target estimates seem to follow a linear layout, estimation  
14  
15 errors for target numbers were more accurate and varied less at and/or around reference  
16  
17 points, which results in a typical *M*-shaped pattern in contour analyses (Ashcraft & Moore,  
18  
19 2012; Cohen & Blanc-Goldhammer, 2011; Link, Huber, et al., 2014). Additionally, use of  
20  
21 reference points and thus proportion-judgement strategies were found to be indexed by (one-  
22  
23 or two-) cyclic power models (Barth & Paladino, 2011; Hollands & Dyre, 2000). Contrary, fit of  
24  
25 cyclic power models was also associated with feedback on the mid-point of the number line  
26  
27 (i.e., 50 by a number line length of 100) provided to participants (Opfer, Siegler, & Young, 2011;  
28  
29 Opfer, Thompson, & Kim, 2016).

30  
31  
32 In sum, all accounts share the idea that several different development-related cognitive skills  
33  
34 and solution strategies are involved in bounded NLE (cf. Barth & Paladino, 2011; Cohen &  
35  
36 Sarnecka, 2014; Ebersbach et al., 2008; Moeller et al., 2009; Siegler & Booth, 2004; Siegler &  
37  
38 Opfer, 2003; Slusser et al., 2013). This is reflected by an ongoing debate on the suitability of  
39  
40 the bounded NLE task as a valid measure of children's number magnitude representation (e.g.,  
41  
42 Cohen & Sarnecka, 2014; Slusser & Barth, 2017), because processes of magnitude estimation  
43  
44 seem to be masked by other cognitive processes and solution strategies involved in performing  
45  
46 the task.  
47  
48  
49  
50  
51  
52  
53  
54  
55  
56  
57  
58  
59  
60  
61  
62  
63  
64  
65

1 In contrast, unbounded NLE is argued to reflect a purer measure of number magnitude  
2  
3 representation (e.g., Cohen & Blanc-Goldhammer, 2011; Link, Huber, et al., 2014; see also  
4  
5 Reinert, Huber, Nuerk, & Moeller, 2015 for eye-tracking evidence supporting this argument)  
6  
7 and seems to be less influenced by age as no development-related performance changes have  
8  
9 been found (Cohen & Sarnecka, 2014; Link, Huber, et al., 2014). This assumption is based on  
10  
11 empirical observations of children of different age levels within primary school and adults. Error  
12  
13 variability in unbounded NLE was found to increase linearly with number magnitude (Cohen &  
14  
15 Blanc-Goldhammer, 2011; Link, Huber, et al., 2014). This finding was interpreted to reflect the  
16  
17 strategic procedure of estimating a multiple of the given unit distance (i.e., dead-reckoning  
18  
19 strategy as suggested by Cohen & Blanc-Goldhammer, 2011 or a counting-like strategy as  
20  
21 recommended by Schneider et al., 2018), which leads to an accumulation of estimation errors  
22  
23 (Reinert et al., 2015). As such, it was argued that unbounded NLE reflects a more direct type of  
24  
25 number magnitude estimation (Link, Huber, et al., 2014, Reinert et al., 2019; but see Kim &  
26  
27 Opfer, 2017). Cohen & Blanc-Goldhammer (2011) showed first evidence that dead-reckoning  
28  
29 strategy, for instance, is indicated by a repetitive scalloped estimation pattern.

#### 41 *Number line estimation and basic arithmetic*

42  
43 Numerous studies have examined associations of bounded and/or unbounded NLE and basic  
44  
45 arithmetic. These studies have shown significant correlations, but only for the bounded version  
46  
47 of the task (e.g., Link, Huber, et al., 2014; Schneider et al., 2018). Bounded NLE performance  
48  
49 significantly predicts mathematical achievement concurrently but also longitudinally (e.g.,  
50  
51 Booth & Siegler, 2008; Schneider, Grabner, & Paetsch, 2009; but see Simms et al., 2016, for  
52  
53 methodological aspects) and correlates with counting, basic arithmetic and algebra as well as  
54  
55 with school achievement and grades (Schneider et al., 2018, for a meta-analysis) from  
56  
57  
58  
59  
60  
61  
62  
63  
64  
65

1 kindergarten to primary school (Booth & Siegler, 2006). In this vein, Friso-van den Bos et al.  
2  
3  
4 (2015) argued that these associations may occur due to a mutual relation between both basic  
5  
6 arithmetic and NLE skills in numerical development: With increasing practice in solving  
7  
8 mathematical problems in childhood, the representation of number magnitude becomes more  
9  
10 accurate, which is in turn reflected in better NLE performance.  
11  
12

13  
14 Comparing data from both versions of the NLE task, Cohen and Sarnecka (Cohen & Sarnecka,  
15  
16 2014) argued that bounded and unbounded NLE should to be associated with different basic  
17  
18 arithmetic skills. The authors found that young children (i.e., preschoolers) underperformed in  
19  
20 bounded NLE, but were able to cope with the unbounded version approximately as well as  
21  
22 older children. Cohen and Sarnecka (2014) concluded that unbounded NLE may be less  
23  
24 demanding, probably because task solution requires less advanced basic arithmetic skills (i.e.,  
25  
26 addition and multiplication) for using dead-reckoning strategies as compared to bounded NLE  
27  
28 (i.e., subtraction and division) for applying proportion judgement strategies.  
29  
30  
31  
32  
33

34  
35  
36 Contrasting bounded and unbounded NLE performance in a sample of fourth-graders, the  
37  
38 study of Link, Nuerk and Moeller (2014) partially confirmed these theoretical assumptions. The  
39  
40 authors argued that bounded NLE may require a division of the number line to guide the  
41  
42 application of proportion-based strategies by reference points. Subsequently, starting from a  
43  
44 reference point, a leftward (reflecting subtraction) or rightward shift on the number line  
45  
46 (reflecting addition) might be necessary to locate the respective target number correctly upon  
47  
48 the line. This adjustment, however, is not appropriate in unbounded NLE. In this vein, Link and  
49  
50 colleagues (2014) did not observe significant correlations between basic arithmetic and  
51  
52 unbounded NLE in their sample of fourth-graders (but see Reinert et al., 2015 for different  
53  
54 results regarding multiplication). Despite an increasing number of studies directly comparing  
55  
56  
57  
58  
59  
60  
61  
62  
63  
64  
65

1 bounded and unbounded NLE, it is not yet clear how both tasks differ in their associations with  
2  
3 various basic arithmetic operations.  
4  
5

6  
7 However, it is important that the results and assumptions described above are again mainly  
8  
9 based on observations of children from kindergarten to the end of primary school and of  
10  
11 adults, whereas the age group in-between, i.e., secondary school children, has so far largely  
12  
13 been neglected. Crucially, the few studies investigating the relationship between NLE and basic  
14  
15 arithmetic in typically developing secondary school children mainly assessed NLE of fractions  
16  
17 and related estimation performance to either a standardised mathematical school achievement  
18  
19 test (Siegler & Pyke, 2013) or to school grades (Schneider et al., 2009). Only few studies focused  
20  
21 on whole numbers. Some of these studies included rather small sample sizes (32 sixth graders  
22  
23 in Siegler & Opfer, 2003 and 24 sixth graders Thompson & Opfer, 2010) or did not use standard  
24  
25 NLE tasks by evaluating NLE on both negative (-10,000-0) and positive numbers (-1,000-1,000)  
26  
27 in sixth and seventh graders (Young & Booth, 2015).  
28  
29  
30  
31  
32  
33  
34  
35

36 On a neuro-functional level, Berteletti et al. (2015) provided first evidence that bounded NLE  
37  
38 performance correlates with activation of brain areas associated with number magnitude  
39  
40 processing (such as the intraparietal sulcus during single digit subtraction). Nevertheless,  
41  
42 empirical data from secondary school children on unbounded NLE are still missing entirely.  
43  
44 Moreover, so far, there is no comparison of bounded and unbounded NLE in secondary school  
45  
46 children, which also compares the association of bounded and unbounded NLE performance  
47  
48 and basic arithmetic in three consecutive age levels.  
49  
50  
51  
52  
53

### 54 **The current study**

55  
56  
57  
58  
59 The current study focused on bounded and unbounded NLE in secondary school children from  
60  
61 grade 5 to 7. In particular, we investigated whether bounded NLE performance changes  
62  
63  
64  
65

1 between these age groups and aimed at providing first empirical data on how secondary school  
2  
3 children perform in unbounded NLE. For bounded NLE, previous studies assessing number line  
4  
5 estimation beyond primary school used number ranges between 0-1,000 and 0-100,000 (Link,  
6  
7 Huber, et al., 2014; Siegler & Opfer, 2003; Thompson & Opfer, 2010; Young & Booth for  
8  
9 negative numbers, 2015). For unbounded NLE, mainly smaller number ranges up to 20 (Cohen  
10  
11 & Blanc-Goldhammer, 2011; Cohen & Sarnecka, 2014), 29 (Link, Nuerk, et al., 2014; Link, Huber,  
12  
13 et al., 2014), and 50 (Reinert et al., 2015a; Reinert et al., 2015b, Reinert et al., 2019) were used.  
14  
15 Only Kim and Opfer (2017) used number ranges of 0-30/100/1,000 in unbounded NLE.  
16  
17 However, Cohen, Blanc-Goldhammer, and Quinlan (2018) pointed to the actual task design  
18  
19 used by Kim and Opfer (2017): in unbounded NLE, children and adults typically overestimate  
20  
21 target numbers (see also Cohen and Sarnecka, 2014). Hence, the physical number line needs  
22  
23 to leave enough room beyond the largest target number so that participants can demonstrate  
24  
25 not only this bias but also scalar variance in their estimations. This issue demonstrates that it is  
26  
27 impossible to accurately run an unbounded number-line task with large numbers (cf. Kim and  
28  
29 Opfer, 2017).  
30  
31

32  
33 However, in studies directly comparing bounded and unbounded NLE performance either  
34  
35 equal number ranges (Reinert, Huber, Nuerk, & Moeller, 2015, Cohen & Blanc-Goldhammer,  
36  
37 2011; Cohen & Sarnecka, 2014) or different number ranges were applied in both tasks (e.g.,  
38  
39 from 0-100, 0-1,000, and 0-10,000 in bounded NLE and 0-25 in unbounded NLE; Link, Huber,  
40  
41 Nuerk, & Moeller, 2014, Reinert et al., 2018, or 0-49 in unbounded NLE; Reinert et al., 2019).  
42  
43 Crucially, Link and colleagues (2014) provided evidence that participants performed less  
44  
45 accurate in unbounded NLE even though the number range was very small in the unbounded  
46  
47 (i.e., 0-25) as compared to the number range in the bounded NLE task (i.e., 0-10,000).  
48  
49 Considering above described problems with creating an unbounded number line for large  
50  
51  
52

63  
64  
65

1 target values and to tie on previous results, we used the same number ranges as in Link et al.,  
2  
3  
4 (2014) study. Importantly, and different from bounded number line estimation, there do not  
5  
6 seem to be substantial influences of age in unbounded NLE (e.g., Link et al., 2014). In fact,  
7  
8 estimation patterns for all age groups were characterised by estimation errors increasing in  
9  
10 size and in variability with increasing magnitude of the respective target numbers.  
11  
12

13  
14 Furthermore, to address the ongoing debate on which version of the NLE task – bounded or  
15  
16 unbounded – is associated with which basic arithmetic operation, the relation of both bounded  
17  
18 and unbounded NLE with the four basic arithmetic operations (i.e. addition, subtraction,  
19  
20 multiplication, and division) was examined. Based on the findings from previous studies  
21  
22 outlined above, our hypotheses were as follows:  
23  
24  
25  
26

27  
28 First, we expected to find significant differences between bounded and unbounded NLE (cf.  
29  
30 Cohen & Sarnecka, 2014). In particular, mean estimation errors were assumed to be higher in  
31  
32 the unbounded task version (Link, Huber, et al., 2014). Second, regarding developmental  
33  
34 changes, we expected a decline of estimation errors with age for bounded NLE, but no  
35  
36 significant age-related differences in estimation errors for unbounded NLE (Cohen & Blanc-  
37  
38 Goldhammer, 2011; Link, Huber, et al., 2014). Third, we expected children to use proportion-  
39  
40 judgement strategies in bounded but not in unbounded NLE and thus, only bounded NLE  
41  
42 errors to follow a characteristic *M*-shaped distribution pattern (cf. Ashcraft & Moore, 2012). The  
43  
44 use of potential reference points in bounded NLE should be predominantly reflected by cyclic  
45  
46 models that best fit the estimation pattern of children. Finally, based on the theoretical  
47  
48 considerations of Cohen and Sarnecka (2014) and the findings of Link et al. (2014), we assumed  
49  
50 both tasks to be associated with different basic arithmetic skills. In particular, we supposed NLE  
51  
52 performance in the bounded task to be associated with subtraction, addition, and division.  
53  
54  
55  
56  
57  
58  
59  
60  
61  
62  
63  
64  
65

1 However, we did not formulate a well-directed hypothesis for the association of unbounded  
2  
3 NLE performance and basic arithmetic. Results of the present study may help to further clarify  
4  
5 these relations.

1 **METHODS:**  
2  
3

4 ***Participants:***  
5  
6  
7

8 A total of 989 children (463 girls) from 12 German secondary schools participated in this study:  
9  
10 children were recruited from 17 5th grade classes (n=342, mean age: 10.58, SD=8.24 months),  
11  
12 21 6th grade classes (n=383, mean age: 11.67, SD=8.48 months) and 15 7th grade classes  
13  
14 (n=264, mean age: 12.57, SD=8.19 months). Cross-sectional data was collected at two different  
15  
16 survey points (SP1 and SP2). Children were divided into two samples and completed a  
17  
18 computerised assessment of either a bounded (Sample 1 assessed at SP1 and SP2: n=700 [SP1:  
19  
20 n=389 and SP2: n=311] mean age: 11.53, SD=12.47 months) or unbounded (Sample 2 assessed  
21  
22 only at SP2: n=289 mean age: 11.56, SD=12.93 months) NLE task. Each child was examined  
23  
24 once. Furthermore, children's basic arithmetic as well as their spelling skills were assessed as  
25  
26 control variables.  
27  
28  
29  
30  
31  
32

33  
34 Data from 195 children who did not complete either the spelling or the arithmetic tasks (n=94)  
35  
36 or had more than 33% missing data (n= 101) in the NLE tasks after outlier correction were not  
37  
38 considered for further analyses. Finally, complete data of 573 children for the bounded NLE  
39  
40 task and 221 children for the unbounded NLE task entered the analyses.  
41  
42  
43  
44

45  
46 Written informed consent was obtained from parents prior to the study besides children's  
47  
48 verbal assent before actual testing. The study was approved by the local ethics committee (LEK  
49  
50 2014/19) as well as by the school authority.

1        **Tasks and procedure:**  
2  
3

4        Data collection took place during regular classes and lasted about 45 minutes. Arithmetic skills  
5        were assessed separately for each basic arithmetic operation (i.e., addition, subtraction,  
6        multiplication, division) together with either the bounded or unbounded NLE task. Spelling was  
7        examined with respect to most relevant German spelling rules (i.e., capitalization, consonant  
8        doubling, lengthening, rule words) and served as control variable. Children completed the  
9        arithmetic and spelling tasks in counterbalanced order across participants. All stimuli were  
10       presented on a 15.6-inch Lenovo ThinkPad T530 laptop display with a resolution of 1024 x 768  
11       pixels at normal viewing distance and with target items in black against a white background.  
12  
13  
14  
15  
16  
17  
18  
19  
20  
21  
22  
23  
24  
25

26       Task relevant laptop functions (e.g., capitalization, deletion of incorrect entries) were  
27       introduced immediately before the assessment, followed by at least one practice trial for each  
28       task. Instructions were presented both visually and auditory. This procedure ensured that all  
29       children had the same prerequisites to cope with the tasks in the computerised assessment.  
30  
31  
32  
33  
34  
35  
36

37       *Basic arithmetic*  
38  
39  
40

41       Children's basic arithmetic skills in *addition*, *subtraction*, *multiplication*, and *division* were  
42       assessed following this particular order using a production paradigm. Children were asked to  
43       type in the correct result of a presented problem. Overall, 20 problems were presented for each  
44       operation. Stimuli were selected as follows: in *addition* (e.g.,  $36+47=$ \_\_\_) and *subtraction* (e.g.,  
45        $91-67=$ \_\_\_), problems were controlled for problem size for each operation. In particular, in  
46       *addition*, four problems each had a result of the 6th to the 9th decade, two problems from the  
47       5th decade and one problem each from the 2nd to the 4th decade. Half of the problems  
48       required a carry operation. In *subtraction*, ten problems with a result in the range 10-19 were  
49       chosen. The results of the other ten problems fell in the range from 20 to 29. Half of the  
50  
51  
52  
53  
54  
55  
56  
57  
58  
59  
60  
61  
62  
63  
64  
65

1 problems required a borrowing operation. In *multiplication* (e.g.,  $8*7=$ \_\_\_), three problems  
2  
3 each were picked from the tables of 3 to 9 as well as two problems from the table of 5. Neither  
4  
5 ties nor problems in reversed order were presented. For *division* (e.g.,  $56/7=$ \_\_\_), multiplication  
6  
7 problems were reversed. Table A1.1 in Appendix A1 provides an overview of all arithmetic  
8  
9 problems.  
10  
11

### 12 *Number line estimation*

13  
14  
15 Children completed either a bounded (range 0-10,000) or an unbounded (range 0-29) version  
16  
17 of the NLE task. In the bounded and unbounded NLE task, target items were presented on the  
18  
19 left end above the lower bound of the number line. The physical length of the number line was  
20  
21 716 pixels. Children were required to mark the correct position of a given number by means of  
22  
23 the mouse cursor. Number line and target number remained on the screen until a response  
24  
25 was given by a mouse click. Both NLE tasks were preceded by a practice trial (5,000 for the  
26  
27 bounded NLE task and 1 for the unbounded NLE task<sup>2</sup>) to ensure that the children understood  
28  
29 the task and to familiarize the children with the use of the computer mouse. In the practice trial  
30  
31 no feedback was provided on the children's estimation accuracy. In the bounded version (range  
32  
33 0-10,000), a total of 24 target numbers were presented in randomised order (i.e., 74, 135, 1097,  
34  
35 1203, 2137, 2315, 3408, 3476, 4542, 4712, 4798, 4957, 5103, 5239, 5298, 5372, 6594, 6781, 7685,  
36  
37 7812, 8793, 8946, 9786, and 9851). In the unbounded version (range 0-29), participants had to  
38  
39  
40  
41  
42  
43  
44  
45  
46  
47  
48  
49  
50  
51

---

52 <sup>2</sup> Please note that the choice of practice items can be discussed: for bounded NLE, there is an ongoing  
53 debate on how anchoring and targeted practice on the midpoint of the number line is associated with  
54 increased estimation accuracy (Slusser, Santiago, & Barth, 2013; Opfer, Thompson, & Kim, 2016).  
55 However, Dackermann and colleagues (2018) did not observe a reliable effect of explicit midpoint  
56 instruction. In the present study, children located the number serving as practice item (i.e., 5000) on the  
57 number line but did not receive any feedback as to whether their estimate was correct or that the given  
58 number represented the mid-point of the number line. For unbounded NLE, we used the smallest unit  
59 size in the practice trial to ensure that children understand to use (multiples of) the unit size for their  
60 estimation. Again, children did not receive any feedback on their estimate.  
61  
62  
63  
64  
65

1 position 24 numbers on a number line, of which only the start and a unit (i.e., the length  
2  
3  
4 corresponding to 1) but no end-point were indicated. The set of target numbers to be located  
5  
6 ranged from 2 to 25, leaving sufficient distance between the end of the physical line (i.e., 29)  
7  
8 and the largest target number (i.e., 25) as children tend to overestimate in this task.  
9

### 10 11 *Spelling competencies*

12  
13  
14  
15  
16 Spelling assessment followed a writing-to-dictation task which required children to complete  
17  
18 gapped sentences (e.g., "Eine Bananenschale ist ..." [Abfall]; engl. "A banana peel is ..."  
19  
20 [garbage]). First, each sentence was presented auditorily, followed by a repetition of the target  
21  
22 word (depicted in square brackets). Children were instructed to read along the sentences  
23  
24 during dictation, wait until the target word was repeated and then type in the respective target  
25  
26 word. Overall, 55 test words were administered with respect to the following orthographic  
27  
28 rules: capitalization (55 words, e.g., '**A**bfall', [engl. 'garbage']), consonant doubling (21 words,  
29  
30 e.g., 'Ab**f**all', [engl. 'garbage']), lengthening (14 words, e.g., '**Die**b', [engl., 'thief']) and rule words  
31  
32 (i.e., words for which the spelling cannot be derived by the phoneme structure; 14 words, e.g.,  
33  
34 '**L**ok', [engl. 'loco']). In this example, the short vowel is not followed by a double consonant, as  
35  
36 one would assume from the German pronunciation). Table A1.2 in Appendix A1 presents the  
37  
38 entire test material for the spelling assessment. Individual spelling was assessed automatically  
39  
40 as either correct (scored 1) or incorrect (scored 0) with respect to each orthographic rule in  
41  
42 each test word (e.g., '**A**bfall' [engl. 'garbage'] was assessed concerning (inner sentence)  
43  
44 capitalization and consonant doubling; correct spelling of '**A**bfall' leads to a word score of max.  
45  
46 2) resulting in a maximum overall sum score of 104.  
47  
48

55  
56  
57

### 58 **Data Analysis:**

#### 59 60 61 *Estimation accuracy and strategy use*

1 First, to increase comparability of the results, we standardised children's estimation errors by  
2  
3 the length of the respective number line in both tasks. Therefore, children's general estimation  
4  
5 accuracy was analyzed using the percent absolute error as dependent variable ( $PAE = \frac{|Estimate - Target\ number|}{Scale} * 100$ ; cf. Siegler and Booth, 2004). PAE is the standard dependent  
6  
7  
8  
9  
10  
11  
12  
13  
14  
15  
16  
17  
18  
19  
20  
21  
22  
23  
24  
25  
26  
27  
28  
29  
30  
31  
32

53  
54  
55  
56  
57  
58  
59  
60  
61  
62  
63  
64  
65

Consider the following example for the bounded NLE task with the target number 74. When the child locates the number at the position of 234, he or she is 160 units off. The PAE in this example amounts to 1.6% ( $PAE = \frac{|234 - 74|}{10,000} * 100$ ). As PAE does not allow to indicate the pattern of over- and underestimation, we also calculated the mean percent relative estimation error [ $REE = \frac{(Estimate - Target\ number)}{Scale} * 100$ ], which would be +1.6% indicating slight overestimation. For the REE, a value of zero means an accurate estimate. A negative value reflects underestimation, whereas a positive value indicates overestimation.

Furthermore, contour analyses (cf. Ashcraft & Moore, 2012) were conducted separately for each grade to contrast children's estimation errors around and in between potential reference points (e.g. start, end, quartile, and mid points) as an index of the use of proportion-judgement strategies (cf. Ashcraft & Moore, 2012) in bounded NLE. Estimates of the following numbers were pooled to reflect the usage of potential reference points beginning from start (74 and 135) via midpoint (4957 and 5103) to the end point (9851 and 9786). Numbers around the first (2315 and 3408) and third quartile (6781 and 7685) in-between these reference points were combined (cf. Lai Zax & Barth, 2018; for other pooling approaches) In unbounded NLE, use of reference points was not expected as the absence of an end point of the scale prevents the possibility of a reference. Nevertheless, for better comparability of the results, estimates of

1 target numbers around the start (2 and 3), first quartile (7 and 8) mid (13 and 14), third quartile  
2  
3  
4 (19 and 20) and end point (24 and 25) of the number line scale were combined as well. Data  
5  
6 points of the contour analysis were then compared using an analysis of variance (ANOVA).  
7  
8

9  
10 Additionally, we conducted model fittings on children`s individual estimates to validate number  
11  
12 line estimation strategies derived from contour analyses. Data were modeled with Matlab 9.4.0  
13  
14 (MATLAB and Statistics Toolbox Release R2018a, The MathWorks, Inc., Natick, Massachusetts,  
15  
16 United States) using the trust region algorithm for non-linear model fitting.  
17  
18  
19  
20

### 21 *Number line estimation and basic arithmetic*

22  
23

24 Association of number line estimation performance and basic arithmetic operations was  
25  
26 assessed by means of partial correlations. With respect to correlation analyses, the Shapiro–  
27  
28 Wilk test (Shapiro & Wilk, 1965) was conducted in order to assess normal distribution. As  
29  
30 distribution of basic arithmetic and spelling data deviated significantly from normal  
31  
32 distribution, Spearman correlation coefficients were calculated. In particular, semi-partial rank  
33  
34 correlation coefficients of non-parametric data ("Spearman's rho") using the R package ppcor  
35  
36 (Kim, 2015) were calculated to examine the correlation of general accuracy in number line  
37  
38 estimation and in the four basic arithmetic operations (i.e., addition, subtraction, multiplication,  
39  
40 division), controlling for age and spelling ability. In order to validate results, cross-validation  
41  
42 methods were applied. For this purpose, existing samples were randomly divided into two data  
43  
44 sets each. As cross-validation revealed reliable outcomes in line with results for the overall  
45  
46 sample, only latter results are presented below. Cross-validation results are reported in Table  
47  
48 A2 in Appendix A2. Bonferroni-Holm procedure (Holm, 1979) was applied in order to  
49  
50 (adequately) correct for multiple testing.

1 **RESULTS:**

2  
3  
4 In total, complete data sets of 573 children for the bounded NLE task, in particular, 198 fifth  
5 graders (94 female, mean age: 10.48, *SD* = 7.32 months), 231 sixth-graders (105 female, mean  
6 age: 11.69, *SD* = 8.64 months) and 144 seventh-graders (74 female, mean age: 12.54, *SD* =  
7 8.28) entered analyses. For unbounded NLE, 221 data sets were analyzed, this means, data of  
8 86 fifth graders (41 female, mean age: 10.62, *SD* = 8.05 months), 81 sixth-graders (37 female,  
9 mean age: 11.72 *SD* = 8.28 months) and 54 seventh-graders (22 female, mean age: 12.75, *SD*  
10 = 9.30 months). Table 1 provides descriptive information regarding all variables used in the  
11 study.

59  
60  
61  
62  
63  
64  
65

1 Children of the two samples did not differ significantly according to their sum scores in terms  
2  
3 of spelling (5<sup>th</sup> grade:  $t(158.82) = -0.018, p = 0.99$ , 6<sup>th</sup> grade:  $t(144.31) = -1.13, p = 0.26$ , 7<sup>th</sup>  
4  
5 grade:  $t(90.12) = 0.59, p = 0.59$ ) and basic arithmetic (5<sup>th</sup> grade:  $t(160.86) = -0.26, p = 0.79$ , 6<sup>th</sup>  
6  
7 grade:  $t(197.5) = -1.71, p = 0.09$ , 7<sup>th</sup> grade:  $t(100.4) = -0.72, p = 0.47$ ) as assessed with Welch  
8  
9 two sample  $t$ -tests. Moreover, at SP<sub>2</sub> bounded and unbounded NLE performance was assessed  
10  
11 within the same school classes. Thus, school- and classroom related influences (e.g., school  
12  
13 location, class size, teaching style, average math performance) were equal for both groups.  
14  
15  
16  
17  
18

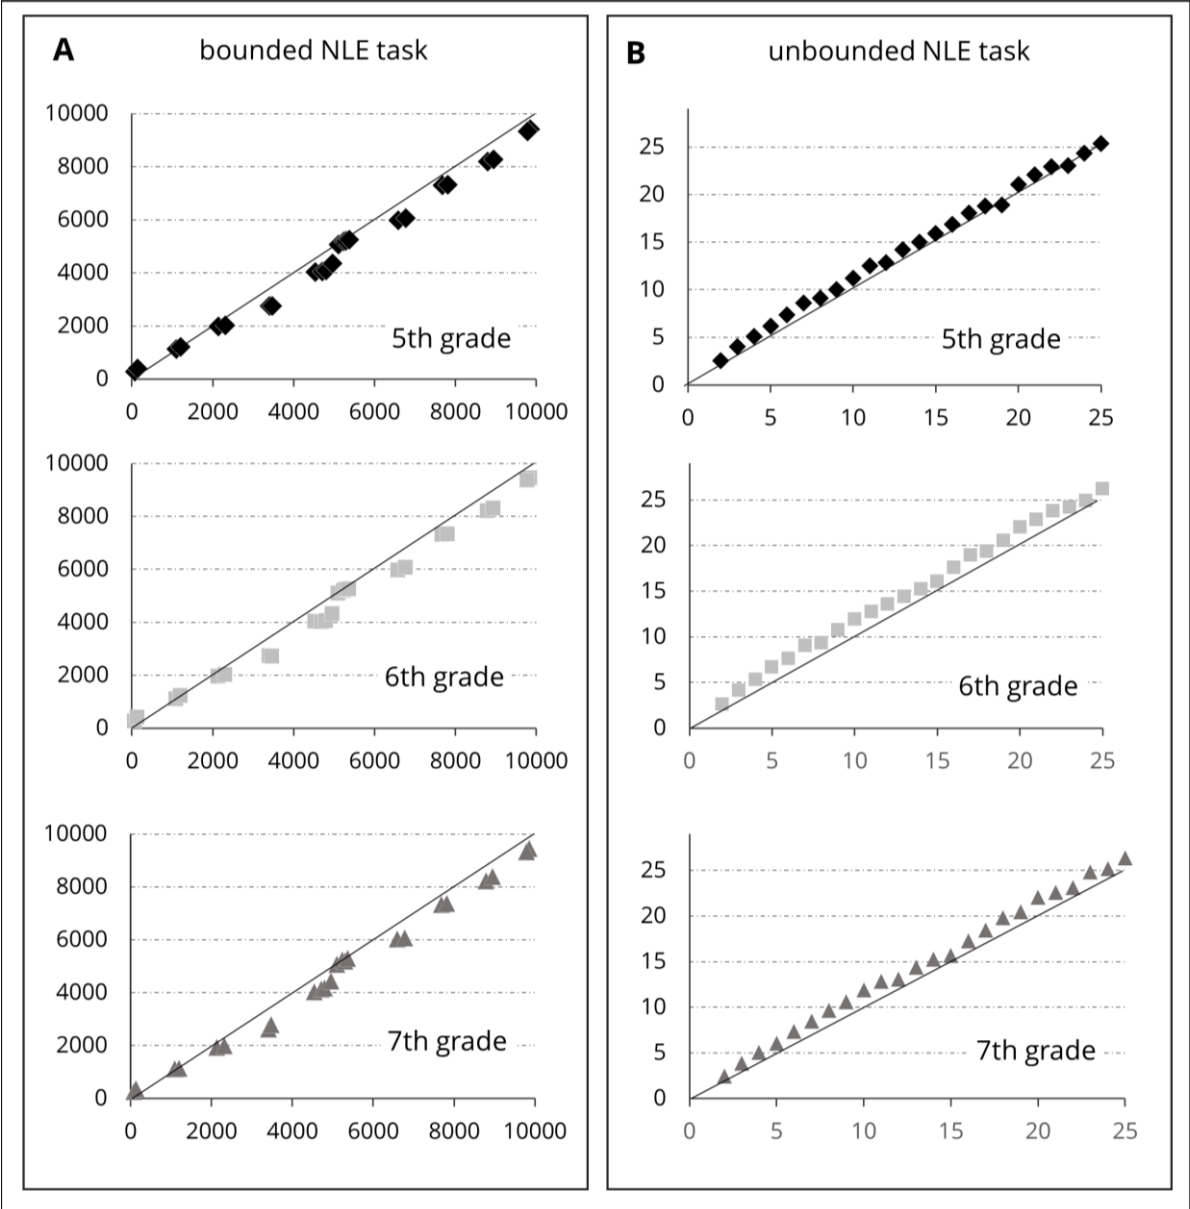

19  
20 A 2 (condition: bounded vs. unbounded NLET) x 3 (5<sup>th</sup> vs. 6<sup>th</sup> vs. 7<sup>th</sup> grade) analysis of variance  
21  
22 (ANOVA) on PAEs revealed a significant main effect for condition [ $F(1,788) = 412.21, p < .001$ ,  
23  
24  $\eta^2_p = 0.35$ ], such that average PAE was significantly lower for bounded NLE ( $M = 5.57, SD =$   
25  
26  $1.49$ ) than for unbounded NLE ( $M = 9.57, SD = 4.07$ ). The main effect for grade [ $F(2,788) = 7.95$ ,  
27  
28  $p < .001, \eta^2_p = 0.02$ ] indicated a significant influence of grade levels on NLE performance.  
29  
30 Furthermore, there was no interaction between condition and group [ $F(2,788) = 0.605, p > 0.05$ ,  
31  
32  $\eta^2_p < 0.01$ ]. Post hoc comparisons for grade using Tukey HSD test applying an adjusted  $p$ -level  
33  
34 for multiple comparisons showed a marginally significant [ $p = .056$ ] difference between mean  
35  
36 PAE of children in the 5<sup>th</sup> ( $M=5.95, SD=1.66$ ) and 7<sup>th</sup> grade ( $M=5.17, SD=1.42$ ), in the bounded  
37  
38 condition. In the unbounded condition, no significant differences in mean PAEs were observed  
39  
40 between grade levels [all  $p > .284$ ; 5-graders ( $M=9.77, SD=4.16$ ), 6-graders ( $M=9.76, SD=4.39$ ),  
41  
42 and 7-graders ( $M=8.97, SD=3.36$ )].

**Figure 1:** Mean estimation pattern for bounded (A) and unbounded (B) number line estimation: The figure shows target values (x-axis) and mean estimates (y-axis) for all three age levels, with  $x=y$  in the diagonal.

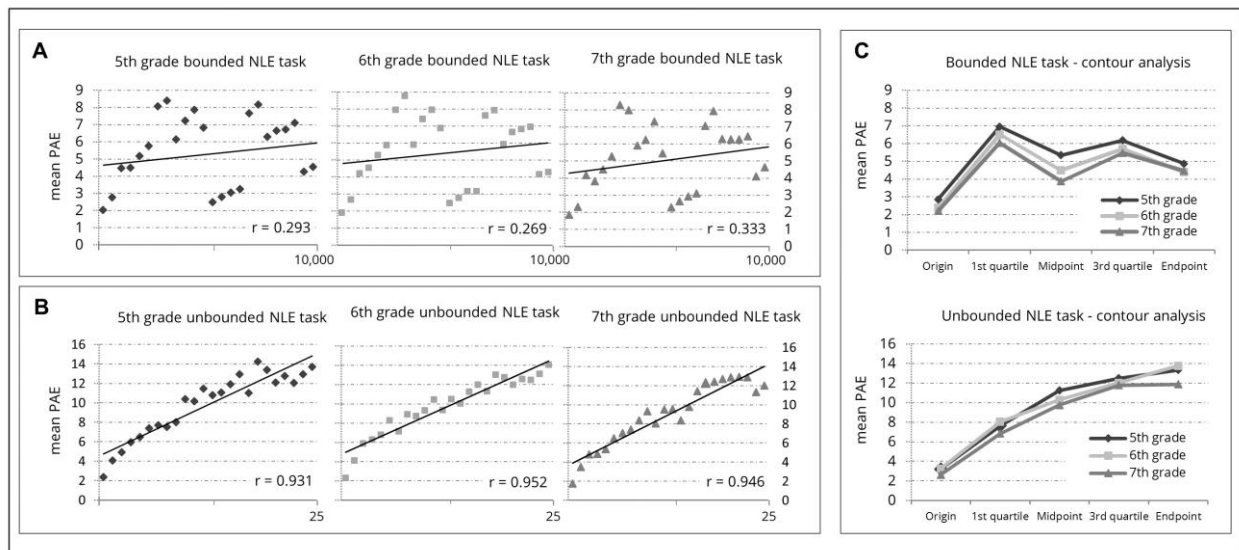

1 Crucially, Figure 1 reveals that estimation patterns differ between bounded and unbounded  
2  
3 NLE: Figure 2 depicts the mean REE score for both bounded and unbounded NLE. Most  
4  
5 importantly, children underestimated target numbers in the bounded NLE task, whereas they  
6  
7 overestimated target numbers in the unbounded NLE task.

30 line estimation performance.  
31

32  
33 Regarding children’s performance in the bounded NLE task Figure 3 revealed estimation errors  
34 to vary for different target numbers. In contrast, children’s estimation errors increased linearly  
35 in the unbounded NLE task. Summarizing estimation errors at/around reference points,  
36 contour analyses revealed an *M*-shaped pattern of error distribution (see Figure 3A) which has  
37 been argued to be characteristic for proportion-judgement strategies (cf. Cohen and Blanc-  
38 Goldhammer, 2011). Correlating PAEs and size of target number revealed no significant  
39 correlations for all grade levels (all  $r < 0.333$ , all  $p > 0.11$ ).

**Figure 3: Mean percentage absolute errors (PAE) for bounded and unbounded number line estimation performance.** The left panel depicts mean PAE and target numbers in the (A) bounded and (B) unbounded NLE task separately for all grade levels. The right panel (C) shows contour analyses summarizing percent absolute errors (PAE) at specific reference points (cf. Ashcraft and Moore, 2012) for all grade levels (i.e., grade 5-7) again for bounded (top) and unbounded (bottom) NLE.

Bonferroni-Holm corrected  $t$ -tests were conducted to compare PAEs at specific reference points (start-, mid- and endpoint) and in the intervals between them (first and third quartile). Results substantiated the descriptive pattern of the contour analyses by indicating significantly reduced PAEs at reference points as compared to the intervals in-between for all grades [5<sup>th</sup> grade:  $t(192) > -7.23, p < .001$ , Cohen's  $d = 0.23 - 1.14$ ; 6<sup>th</sup> grade:  $t(227) > -21.53, p < .001$ , Cohen's  $d = 0.40 - 1.43$ , and 7<sup>th</sup> grade:  $t(142) > -14.79, p < .001$ , Cohen's  $d = 0.37 - 1.23$ ]. In unbounded NLE, in contrast, linearly increasing PAEs across all age groups were observed: PAEs increased monotonically with target number (see Figure 3B) resulting in significant correlations between PAEs and size of target number (from  $r = 0.931$  to  $r = 0.952$ , all  $p < 0.05$ ). This pattern was also found in contour analyses (Figure 3C). Bonferroni-Holm corrected  $t$ -tests revealed significant differences between both the start- and midpoint and the quartile [5<sup>th</sup> grade:  $t(85) > -12.09, p < .001$ , Cohen's  $d = 0.58 - 1.30$ ; 6<sup>th</sup> grade:  $t(80) > -12.09, p < .001$ , Cohen's  $d = 0.25 - 1.50$ , and 7<sup>th</sup> grade:  $t(53) > -10.14, p < .001$ , Cohen's  $d = 0.31 - 1.38$ ], but not for the third quartile and the endpoint [5<sup>th</sup> grade:  $t(85) > -1.64, p > 0.05$ , Cohen's  $d = 0.18$ ; and 7<sup>th</sup> grade:

1  $t(53) > -2.25, p(\text{adj.}) > 0.05$ , Cohen's  $d = 0.01$ ), except for the 6<sup>th</sup> grade ( $t(80) > 2.5432, p < .001$ ,  
2  
3  
4 Cohen's  $d = 0.28$ ].  
5  
6

7 Additionally, we fitted children's number line estimates with different mathematical models.  
8  
9 Table 2 shows absolute and relative frequencies (in parenthesis) of best fitting models for  
10 bounded and unbounded NLE separated for the three different grade levels.  
11  
12  
13  
14  
15

16 In bounded NLE, linear models provided best fit for all grade levels (for 56% of fifth, 55% of  
17 sixth, and 56% of seventh graders). Only about 30% of all children's estimates were best  
18 determined by models indicating proportion-judgement strategies (i.e., one-cyclic or two-  
19 cyclic models), and thus the use of reference points. This finding may contradict evidence for  
20 proportion-judgement from the contour analyses.  
21  
22  
23  
24  
25  
26  
27  
28

29 In unbounded NLE, over 90% of children's estimates were accounted best by linear (for 63% of  
30 the fifth, 68% of the sixth, and 65% of the seventh graders) or power models (for 29% of the  
31 fifth, 30% of the sixth, and 33% of the seventh graders) for all grade levels. Model fitting did  
32 not indicate model fits in favor of dead-reckoning in unbounded number line estimation.  
33  
34  
35  
36  
37  
38  
39  
40 Crucially, and in particular for unbounded NLE, mean adjusted  $R^2$  resp. the AIC values were  
41 almost identical. As such, a unique derivation of the best fitting model seems not feasible.

**Note:** Absolute and relative frequency (percentages) of best fitting models for bounded (A) and unbounded (B) number line estimation separated for grade levels. The best fitting models are indicated in bold script.

Regarding the partially contradictory results of contour analyses and model fittings for bounded NLE, closer visual examination of children’s individual estimation pattern was more revealing. Table 3 provides results of individual contour analysis for each child separated for the best fitting models as well as for grade level. The table differentiates between the M-shape pattern of number estimates and other patterns (i.e., N-shape, inverse N-shape, V-shape, etc.). At first glance, more than one third of fifths and sixth graders showed an M-shape estimation pattern on the individual level. This number increased in the seventh grade up to almost fifty percent indicating an increasing use of reference points with age. Yet, these findings cannot be clearly derived from the results of individual model fittings: successful use of reference points (i.e., proportion-judgement) and thus minimal estimation errors can be also accounted by linear models (e.g., Link, Huber, et al., 2014). Contrary, unsuccessful use of reference points (i.e., a V-shape or N-shape pattern) can be accounted by one- or two-cyclic models.

**Table 3:** Individual contour analyses and model fittings for bounded NLE

	5th grade		6th grade		7th grade	
	M-Shape	Other	M-Shape	Other	M-Shape	Other
linear model	41	71	50	78	40	41
power model	8	24	10	17	8	12
one-cyclic model	8	23	14	21	13	10
two-cyclic model:	6	17	9	32	6	14
$\Sigma$	63 (32)	135 (68)	83 (36)	148 (64)	67 (47)	77 (53)

**Note:** Absolute and relative frequency (percentages) for the use of proportion-judgement strategy (i.e., M-Shape estimation pattern) or other strategies derived from contour analysis in bounded number line estimation.

### *Number line estimation and basic arithmetic*

First, we analyzed to what extent spelling and arithmetic skills were associated to control for influences of general cognitive abilities in subsequent analyses. Partial correlations controlling for age revealed relatively high correlations between basic arithmetic skills and overall spelling skills for both samples assessed with the bounded ( $n=573$ ,  $r=.51$ ,  $p<.001$ ) and unbounded ( $n=221$ ,  $r = .43$ ,  $p<.001$ ) NLE task. These correlations indicated a strong association between spelling and arithmetic performance. As spelling and arithmetic skills have been found to rely on common general cognitive abilities (e.g., working memory, verbal memory, and reasoning skills, e.g., Kniewel, Daseking, & Petermann, 2010; Passolunghi, Mammarella, & Altoè, 2008), we used overall spelling skills as a proxy to control for influences of general cognitive ability. Subsequently, partial correlations were calculated controlling for age and spelling skills. Table 4 shows the results of the partial correlation between number line estimation performance and basic arithmetic separately for grade levels. For bounded NLE, strength of correlations increased with age. In grade 5, NLE performance correlated significantly with subtraction (i.e., lower error rate in subtraction problems was associated with less estimation errors in NLE), but not with addition, multiplication, or division. In grade 6, significant correlations were found for addition, subtraction and multiplication, but not for division. In grade 7, bounded NLE

performance was found to be significantly associated with all basic arithmetic operations, but highest with addition and subtraction. For unbounded NLE, no significant correlation was found between task performance and basic arithmetic.

**Table 4:** Partial correlations (one-tailed) between PAEs of bounded (left panel) and unbounded NLE and basic arithmetic

<i>Grade</i>	<b>Bounded NLE task</b>				<b>Unbounded NLE task</b>			
	<i>Add</i>	<i>Sub</i>	<i>Mul</i>	<i>Div</i>	<i>Add</i>	<i>Sub</i>	<i>Mul</i>	<i>Div</i>
5 <sup>th</sup> grade	-0.09	<b>-0.20**</b>	-0.08	-0.03	0.06	-0.14	0.03	-0.06
6 <sup>th</sup> grade	<b>-0.29**</b>	<b>-0.23**</b>	<b>-0.21**</b>	-0.06	-0.08	-0.05	0.02	0.06
7 <sup>th</sup> grade	<b>-0.43**</b>	<b>-0.44**</b>	<b>-0.24**</b>	<b>-0.25*</b>	0.03	-0.17	0.14	0.05

**Note:** Overall partial correlations were calculated for all grade levels. Add=Addition, Sub=Subtraction, Mul=Multiplication, Div=Division. \*  $p < .05$ , \*\*  $p < .001$ .

1 **DISCUSSION:**  
2  
3

4 In the following, we discuss results on number line *estimation accuracy and strategy use* and  
5 the association of *NLE and basic arithmetic* separately with regard to the relevant literature.  
6  
7

8  
9  
10 *Estimation accuracy and strategy use*  
11

12  
13 Results of the current study substantiated that secondary school children performed differently  
14 in bounded and unbounded NLE: PAEs were almost twice as high in unbounded than in  
15 bounded NLE. These findings are consistent with previous results on primary school children  
16 (i.e., grade 3 and 4) and adults (e.g., Link, Huber, et al., 2014, Reinert et al., 2019; for a production  
17 version of the task). Importantly, this result cannot be explained by the different number ranges  
18 used in the present study for unbounded and bounded NLE. Although one may assume that  
19 all children were familiar with both intervals, the larger number interval should nevertheless be  
20 more error prone due to the problem size effect (Zbrodoff & Logan, 2005, for a review).  
21  
22 However, mean estimation errors in bounded NLE were significantly lower. More likely, the  
23 difference in estimation accuracy arises from different solutions strategies applied. In bounded  
24 NLE, application of proportion-based strategies simplifies task solution; the presence of a start  
25 and an end point facilitated the derivation of the center of the number line and also  
26 decomposition into sections. This procedure reduces the number of mistakes made by the  
27 children. Thus, estimation errors were reduced. Unbounded NLE does not offer this solution  
28 strategy as the end point is missing.  
29

43  
44  
45  
46  
47  
48  
49  
50  
51  
52

53 Contour analysis in the present study substantiated this assumption. In line with Ashcraft and  
54 Moore (2012) as well as with Link et al. (2014), a characteristic *M*-shaped pattern of estimation  
55 errors (i.e., smaller and less variable estimation errors for target numbers at or around reference  
56 points) was observed in contour analyses for bounded NLE. This suggested that children used  
57  
58  
59  
60  
61  
62  
63  
64  
65

1 proportion-based strategies to solve the task. By contrast, we observed an almost linearly  
2  
3 increasing error pattern for unbounded NLE, which has been previously assumed to be related  
4  
5 to a magnitude estimation-based strategy in unbounded NLE (Cohen & Blanc-Goldhammer,  
6  
7 2011; Link, Huber, et al., 2014). However, a closer look at the potential reference in the  
8  
9 unbounded NLE tasks disclosed that the children may not have been able to express their  
10  
11 entire estimation bias (with overestimating target numbers by about 50%, cf. Cohen &  
12  
13 Sarnecka, 2014) because of the length of the physical number line (i.e., 716 pixels  
14  
15 corresponding to 29 units). This might explain the lack of significant further increase in  
16  
17 estimation error for target numbers in the 3<sup>rd</sup> quartile and at around the end point (i.e., target  
18  
19 numbers larger than 20). However, we are confident that this does not affect general  
20  
21 conclusions made about solution strategies in unbounded NLE. Nevertheless, future studies  
22  
23 should be aware of the necessity to provide a sufficiently long physical number line (depending  
24  
25 on the number ranged used) to be able to assess the respective (over)estimation bias.  
26  
27

28  
29 However, these findings were only partially corroborated by model fitting results. Model  
30  
31 fittings for bounded NLE indicated best fit of linear models for the majority of children's  
32  
33 estimates. As recently discussed by Link and colleagues (2014), a very accurate estimation  
34  
35 pattern can hardly be differentiated by model fittings. Contrarily, model fitting results for  
36  
37 unbounded NLE were unambiguous. They did not provide any evidence for specific strategy  
38  
39 use (i.e., proportion-judgement) in unbounded number line estimation.

48  
49  
50

51  
52 Furthermore, as with primary school children (e.g., Barth & Paladino, 2011; Cohen & Blanc-  
53  
54 Goldhammer, 2011; Link, Huber, et al., 2014; Slusser & Barth, 2017), estimation accuracy in the  
55  
56 present study was found to improve with age for bounded NLE. In contrast, for unbounded  
57  
58 NLE no significant differences in estimation accuracy was observed across grade levels.  
59  
60  
61  
62  
63  
64  
65

1 However, we observed age-related increases from 5th to 7th grade for both basic arithmetic  
2 and spelling performance which were considered as control variables. Considering the  
3 observation that estimation performance does not change in unbounded NLE across the  
4 different age groups, the question arises to what extent unbounded NLE performance is  
5 influenced by general age-related developmental processes.

12

### 13 *Number line estimation and basic arithmetic*

14  
15 Results substantiated an association of NLE performance for bounded but not unbounded NLE  
16 and basic arithmetic (cf. Cohen & Sarnecka, 2014; Link et al., 2014). Correlation coefficients  
17 were comparable to those reported in other studies (ranging from  $r = 0.29 - 0.86$ ) relating  
18 various mathematical competencies (i.e., problem solving, calculation; see Schneider et al.,  
19 2018, for an overview). In particular, we observed subtraction skills to be associated with  
20 bounded NLE performance consistently for all grades. In grade 6, correlations with addition  
21 and multiplication were of equal strength as with subtraction. In grade 7, all four arithmetic  
22 operations were significantly associated with bounded NLE.

37  
38  
39

40 We suggest that children who are well versed in solving subtraction tasks may be more likely  
41 to successfully use proportion-judgement strategies. The following factors might contribute to  
42 this finding: First, addition and subtraction are taught as the first arithmetic operations in  
43 school (e.g., Bildungsplan Sekundarstufe I, Ministerium für Kultus, Jugend und Sport, Baden  
44 Württemberg, 2016). However, subtraction is regarded to be more demanding as compared to  
45 addition (e.g., because of borrowing, Artemenko et al., 2018), and children were found to use  
46 calculation (i.e., instead of fact retrieval in simple addition and multiplication problems) to solve  
47 subtraction problems even in 2-digit numbers (e.g., Ischebeck et al., 2006). Thus, subtraction  
48 might be more sensitive to reflect differences in magnitude estimation skills as it also relies on  
49  
50  
51  
52  
53  
54  
55  
56  
57  
58

60  
61  
62  
63  
64  
65

1 magnitude manipulations to a higher degree. Second, according to the proportion-judgement  
2  
3 account, a leftward (reflecting subtraction) or rightward shift (reflecting addition) starting from  
4  
5 a reference point might be necessary to locate the number correctly upon the line (cf. Cohen  
6  
7 and Sarnecka, 2014). A closer descriptive look at the results of the contour analysis (Figure 3)  
8  
9 and mean PAEs at the quartiles supports this assumption: starting from the mid-point, a  
10  
11 leftward shift (from mid-point to the first quartile reflecting subtraction) resulted in higher  
12  
13 estimation errors than a shift to the right (from mid-point to the third quartile reflecting  
14  
15 addition). Third, further evidence may be derived from neuro-functional level: Berteletti and  
16  
17 colleagues (2015) demonstrated that activation of brain areas associated with number  
18  
19 magnitude processing (as required in subtraction) were correlated with NLE performance.  
20  
21 Furthermore, Ischebeck et al. (2006) provided neuro-functional evidence that a training of  
22  
23 subtraction problems in young adults encouraged the application of efficient procedural  
24  
25 solution strategies. This result suggests that children with high subtraction skills are more likely  
26  
27 to apply sufficient solution strategies (i.e., proportion-judgement) at least in bounded NLE.  
28  
29  
30  
31  
32  
33  
34  
35  
36  
37

38 An explanation for significant associations between bounded NLE and multiplication as well as  
39  
40 division occurring not before grade 6 and 7, respectively, might be that, according to German  
41  
42 math curricula, multiplication and division are increasingly used with the introduction of  
43  
44 fractions in grade 6 (e.g., Bildungsplan Sekundarstufe I, Ministerium für Kultus, Jugend und  
45  
46 Sport, Baden Württemberg, 2016). Although all four basic arithmetic operations have already  
47  
48 been acquired in primary school (i.e., before grade 5; Huber, Moeller, & Nuerk, 2012), the  
49  
50 increasing significance of multiplication and division (i.e., fractions) from grade 6 onwards  
51  
52 might enable children to apply proportion-judgement strategies more proficiently, leading to  
53  
54 better performance in bounded NLE. Visual inspection of contours on individual levels  
55  
56 confirmed the increasing use of reference points with age. This in turn can influence NLE  
57  
58  
59  
60  
61  
62  
63  
64  
65

1 performance as presented by Siegler and colleagues (2011) in another domain of mathematics  
2  
3 (i.e., fractions) showing that segmentation strategies involving dividing up the number line with  
4  
5 subjective landmarks leads to more accurate fraction number line estimates.  
6  
7

8  
9 Moreover, correlation coefficients became stronger for subtraction, addition, multiplication  
10  
11 and finally division from grade 5 to 7, suggesting an increasing importance of basic arithmetic  
12  
13 for bounded NLE. These findings substantiate the assumption of Friso-van den Bos et al. (2015)  
14  
15 who argued that associations between arithmetic skills and NLE are predominantly driven by  
16  
17 developmental processes.  
18  
19  
20  
21

22  
23 For the association of unbounded NLE performance and basic arithmetic, we did not find  
24  
25 significant relations with any basic arithmetic operation in secondary school children (Link et  
26  
27 al., 2014; for similar results). Building on the results of Cohen and Blanc-Goldhammer (2011)  
28  
29 and Reinert et al. (2015), we would have expected at least a weak correlation of unbounded  
30  
31 NLE with addition and multiplication, respectively. Even though, and unlike Reinert et al. (2015),  
32  
33 we did neither focus on analyzing different unit distances (0-1, 0-5, etc.) nor specifically  
34  
35 selected multiples of these as target numbers. However, the lack of associations between  
36  
37 unbounded NLE and basic arithmetic seems plausible considering the assumption that  
38  
39 unbounded NLE may be solved by iterative counting like strategies (Reinert et al., 2015;  
40  
41 Schneider et al., 2018). Counting as a highly automated process may not depend on basic  
42  
43 numerical and arithmetical skills. In this vein, unbounded NLE seems to reflect purer numerical  
44  
45 estimation, which may be superimposed less by underlying arithmetic processes (i.e., addition,  
46  
47 subtraction, division) of other solution strategies as is proportion-judgement (see also Cohen  
48  
49 & Blanc-Goldhammer, 2011; Link, Huber, et al., 2014; Reinert et al., 2015). In sum, the present  
50  
51 data provide additional evidence from secondary school children that unbounded number line  
52  
53  
54  
55  
56  
57  
58  
59

61  
62  
63  
64  
65

1 estimation may indeed be solved primarily based on processing and estimating number  
2  
3 magnitude.  
4  
5

6  
7 When interpreting these results, there are some constraints that need to be considered. First,  
8  
9 in the present study different number ranges were used in bounded (0-10,000) and unbounded  
10  
11 (0-29) number line estimation to tie on results of previous studies (e.g., Link, Huber, et al., 2014;  
12  
13 Siegler & Opfer, 2003; Thompson & Opfer, 2010). As introduced above, there are sensible  
14  
15 reasons for using larger number ranges for bounded NLE and to use small number ranges in  
16  
17 unbounded NLE (e.g., Cohen et al., 2018). However, to enhance comparability of results,  
18  
19 standardised measures considering the length of the respective number lines were used (see  
20  
21 also Link, Huber, et al., 2014; for a methodological discussion on the application of different  
22  
23 number ranges). This approach seems warranted as we did not draw any conclusions on  
24  
25 differences in task difficulty between differently large number ranges.  
26  
27  
28  
29  
30  
31  
32

33  
34 Second, the study was cross-sectional, so we did not monitor intra-individual development in  
35  
36 bounded and unbounded NLE. However, conclusions on numerical development with age  
37  
38 seem warranted as for both spelling and basic arithmetic tasks our data documented increasing  
39  
40 performance with increasing age. Nevertheless, it would be desirable to pursue intra-individual  
41  
42 developmental changes in estimation accuracy in secondary school children more  
43  
44 systematically in future studies.  
45  
46  
47  
48  
49

50  
51 Third, as we assessed performance in bounded and unbounded NLE inter-individually, direct  
52  
53 comparisons of both NLE tasks within one child were not possible. Nevertheless, both samples  
54  
55 seem well comparable as bounded and unbounded NLE was assessed within the same school  
56  
57 classes (at least at SP<sub>2</sub>), and thus, class-room related influences (e.g., class size, teaching style,  
58  
59 average math performance of the school class) were equally distributed across both groups.  
60  
61  
62  
63  
64  
65

1 Moreover, and this is particularly important, the two groups solving either bounded or  
2  
3 unbounded NLE neither differed significantly in mean basic arithmetic skills nor in spelling  
4  
5 performance. We therefore assume that both groups are well comparable and sufficient to  
6  
7 draw comparable conclusions on bounded and unbounded NLE performance. However,  
8  
9 individual comparisons would be desirable for future studies. Finally, it is not clear yet whether  
10  
11 and how the presentation medium (i.e., computerised assessment in the current study)  
12  
13 moderates NLE (Schneider et al., 2018), and potentially leads to inconsistent results (e.g.,  
14  
15 increased error variability) as compared to earlier paper-pencil studies. Future mode effect  
16  
17 studies on NLE comparing computerised and paper-pencil testing could provide further  
18  
19 insights.

1 **CONCLUSIONS:**

2  
3  
4 In the current study, we investigated bounded and unbounded NLE in secondary school  
5 children (i.e., grade 5 to 7). We found that children’s performance in bounded NLE was  
6 significantly better as compared to unbounded NLE for all grade levels. Moreover, estimation  
7 accuracy seems to improve with age only in the bounded, but not in the unbounded task  
8 version. With respect to the association of NLE performance with basic arithmetic, we observed  
9 that estimation performance in bounded but not unbounded NLE was strongly associated with  
10 basic arithmetic operations (i.e., addition, subtraction, multiplication, division). Interestingly,  
11 these associations increased with age, and thus, are probably subject to developmental  
12 changes. With respect to solution strategies employed in NLE, current results corroborated the  
13 assumption of bounded but not unbounded NLE to rely on proportion-based estimation  
14 strategies.

28  
29  
30  
31

32  
33  
34 In summary, these data indicate that differential results on the association between bounded  
35 and unbounded NLE with arithmetic operations obtained in primary school generalize to older  
36 secondary school children. Thereby, our results substantially contribute to the knowledge  
37 about the (consecutive) development of skills pertaining to bounded and unbounded number  
38 line estimation, as they provide additional evidence for the assumption that unbounded NLE  
39 may indeed reflect a more direct and pure measure of number magnitude estimation.

## APPENDIX A1

Appendix A1 provides test material used to assess basic arithmetic (Table A1.1) and spelling competencies (Table A1.2) of this study.

**Table A1.1:** Basic arithmetic problems

N	Addition	Subtraction	Multi- plication	Division
P	$12 + 3 = 15$			
1	$36+47 = 83$	$91-67 = 24$	$8 \times 7 = 56$	$48 \div 6 = 8$
2	$29+67 = 96$	$93-67 = 26$	$8 \times 6 = 48$	$56 \div 7 = 8$
3	$25+67 = 92$	$51-37 = 14$	$8 \times 4 = 32$	$32 \div 4 = 8$
4	$21+27 = 48$	$94-69 = 25$	$7 \times 6 = 42$	$54 \div 9 = 6$
5	$65+28 = 93$	$92-76 = 16$	$9 \times 7 = 63$	$42 \div 6 = 7$
6	$29+38 = 67$	$81-65 = 16$	$6 \times 9 = 54$	$63 \div 7 = 9$
7	$38+25 = 63$	$41-18 = 23$	$4 \times 7 = 28$	$24 \div 8 = 3$
8	$27+29 = 56$	$45-29 = 16$	$4 \times 6 = 24$	$72 \div 8 = 9$
9	$24+68 = 92$	$52-27 = 25$	$4 \times 9 = 36$	$35 \div 5 = 7$
10	$46+36 = 82$	$33-18 = 15$	$3 \times 8 = 24$	$21 \div 3 = 7$
11	$53+36 = 89$	$96-72 = 24$	$9 \times 8 = 72$	$18 \div 3 = 6$
12	$42+34 = 76$	$97-71 = 26$	$3 \times 9 = 27$	$36 \div 9 = 4$
13	$65+21 = 86$	$36-14 = 22$	$5 \times 8 = 40$	$28 \div 7 = 4$
14	$28+51 = 79$	$76-62 = 14$	$3 \times 4 = 12$	$40 \div 8 = 5$
15	$37+41 = 78$	$39-26 = 13$	$7 \times 5 = 35$	$24 \div 6 = 4$
16	$24+45 = 69$	$29-16 = 13$	$6 \times 3 = 18$	$27 \div 9 = 3$
17	$41+35 = 76$	$56-41 = 15$	$7 \times 3 = 21$	$12 \div 4 = 3$
18	$15+13 = 28$	$38-21 = 17$	$6 \times 5 = 30$	$30 \div 5 = 6$
19	$13+24 = 37$	$39-11 = 28$	$5 \times 4 = 20$	$20 \div 4 = 5$
20	$41+13 = 54$	$27-13 = 14$	$5 \times 3 = 15$	$15 \div 3 = 5$

**Note:** Basic arithmetic problems were preceded by one practice trial (P) to familiarize the children with the computerised testing.

**Table A1.2:** Spelling competencies assessed by gapped sentences

46	stumm	x	x	Ich hatte einen Schock, konnte nichts sagen und blieb ganz ...	I was in shock, couldn't say anything and remained completely ... (mute).
47	stützt	x	x	Der Kranke ... sich auf die Krücke	The patient ... on the crutch. (leans)
48	treffen	x	x	Können wir uns in der Pause auf dem Hof ...	Can we ... on the yard during the break. (meet)
49	Üben	x		Ohne ... wird keiner ein Meister	Without ..., no one will be a master. (practice)
50	Überschwemmung	x	x	Wenn ein Fluss über die Ufer tritt, gibt es eine...	When a river bursts its banks, there is a ... (flood)
51	verspritzen	x	x	Beim Patronenwechsel bin ich vorsichtig, ich will die Tinte nicht...	I'm careful when changing cartridges; I don't want to ... the ink. (splash)
52	verwöhnt	x	x	Meine Schwester ist ein Nesthäkchen, sie wird meistens...	My sister is a nestling, she is usually ... (pampered)
53	voll	x	x	Schenke mir mein Glas bitte ganz...	Give me a ... glass, please. (full)
54	Zaubertrick	x	x	Wer ein Kaninchen aus einem Hut holt, kann einen ...	When you take a rabbit out of a hat, you can do a ... (magic trick)
55	Zwerg	x		Im Märchen taucht oft ein kleiner... auf.	A little ... often appears in fairy tales. (dwarf)

**Note:** Test words and corresponding sentences are presented in alphabetic order. The table also specifies which German spelling rules appear in which test word (C= capitalization, D= consonant doubling, L=lengthening, R=rule words). The English translation is intended to give the interested non-German-speaking reader an impression of the used test material. However, it is not suitable to reflect the particular characteristics of the German orthographic rules for the test words in the spelling assessment.

1 **APPENDIX A2**

2  
3  
4 In order to validate results of partial correlation analyses, cross-validation methods were  
5  
6 applied. For this purpose, existing samples were randomly divided into two data sets ( $n_1$  and  
7  
8  $n_2$ ) for the bounded and unbounded NLE task.  
9

10  
11  
12 First, associations of spelling and basic arithmetic in the overall sample were compared to the  
13  
14 two sub samples. Partial correlations controlling for age revealed relatively high correlations  
15  
16 between basic arithmetic skills and spelling skills in both samples assessing bounded ( $n=573$ ,  
17  
18  $r=.51$ ,  $p<.001$ ) and unbounded ( $n=221$ ,  $r = .43$ ,  $p<.001$ ) NLE performance. Cross-validated  
19  
20 correlations were found to be similarly highly correlated (bounded NLET:  $n_1=287$ ,  $r_1=.43$ ,  
21  
22  $p_1<.001$ ,  $n_2=286$ ,  $r_2=.49$ ,  $p_2<.001$ ; unbounded NLET:  $n_1=111$ ,  $r_1=.41$ ,  $p_1<.001$ ,  $n_2=110$ ,  $r_2=.42$ ,  
23  
24  $p_2<.001$ ) and confirmed us to use overall spelling ability as a proxy to control for influences of  
25  
26 general cognitive ability.  
27  
28  
29  
30  
31  
32

33  
34 **Table A2:**

35  
36  
37 Cross-validated partial correlations (one-tailed) between bounded (upper panel) and  
38  
39 unbounded NLE task and basic arithmetic abilities  
40  
41

		A) Bounded NLE task				B) Unbounded NLE task			
Grade	Sample	Add	Sub	Mul	Div	Add	Sub	Mul	Div

	Sub 2	-0.02	-0.16*	-0.06	0.04	0.18	0.12	0.33	0.26
6 <sup>th</sup> grade	Overall	-0.29**	-0.23**	-0.21**	-0.06	-0.08	-0.05	0.02	0.06
	Sub 1	-0.29**	-0.23**	-0.21*	-0.06	0.03	0.14	0.08	-0.08
	Sub 2	-0.35**	-0.29**	-0.29*	-0.12	-0.08	-0.01	-0.02	0.09
7 <sup>th</sup> grade	Overall	-0.43**	-0.44**	-0.24**	-0.25*	0.03	-0.17	0.14	0.05
	Sub 1	-0.52**	-0.39**	-0.26*	-0.33**	0.40	0.10	0.08	0.25
	Sub 2	-0.42**	-0.44**	-0.31*	-0.28**	0.19	-0.32	0.24	0.09

42  
43  
44  
45  
46  
47  
48  
49  
50  
51  
52  
53  
54  
55 **Note:** Overall and cross-validated (Sub 1 and Sub 2) partial correlations were calculated for all grade  
56  
57 levels. Add=Addition, Sub=Subtraction, Mul=Multiplication, Div=Division. \*  $p<.05$ , \*\*  $p<.001$ .  
58  
59  
60  
61  
62  
63  
64  
65

1 Second, partial correlations controlling for age and spelling skills were performed separately  
2  
3 for all grade levels. Table A2 in Appendix A2 shows the results of partial correlations between  
4  
5 number line estimation and basic arithmetic for the overall and the sub samples. Subsequently,  
6  
7 correlation coefficients in the two random sub-samples ( $n_1$  and  $n_2$ ) were compared to the  
8  
9 correlation coefficient of the overall sample ( $n$ ) applying Student's t-distribution (Lenhard &  
10  
11 Lenhard, 2014). Comparisons revealed no significant differences in both bounded (for all  
12  
13 comparisons,  $z > -.925$ ,  $p > .10$ ) and unbounded number line estimation (for all comparisons,  
14  
15  $z < 1.635$ ,  $p > .05$ ). This finding could prove the correlation coefficients in the overall sample as  
16  
17  
18  
19  
20  
21  
22 reliable.

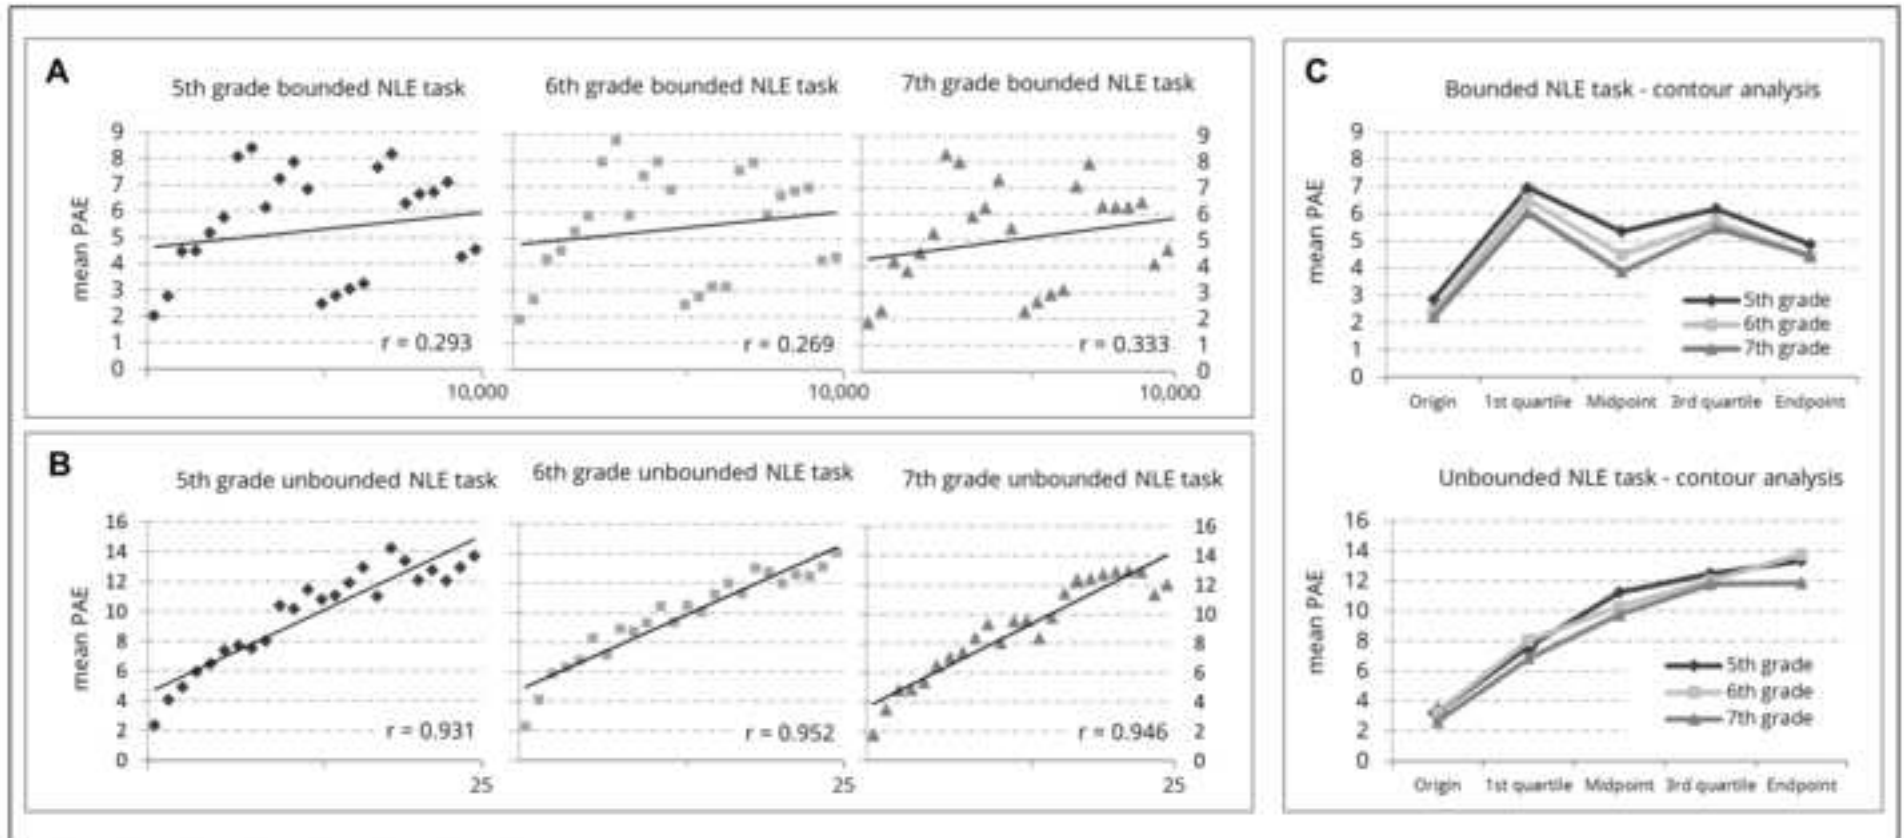

Figure 1

**Figure 1:** Mean estimation pattern for bounded (A) and unbounded (B) number line estimation: The figure shows target values (x-axis) and mean estimates (y-axis) for all three age levels, with  $x=y$  in the diagonal.

**Figure 2:** Mean relative estimation errors (REE) for bounded and unbounded number line estimation performance.

**Figure 3:** Mean percentage absolute errors (PAE) for bounded and unbounded number line estimation performance. The left panel depicts mean PAE and target numbers in the (A) bounded and (B) unbounded NLE task separately for all grade levels. The right panel (C) shows contour analyses summarizing percent absolute errors (PAE) at specific reference points (cf. Ashcraft and Moore, 2012) for all grade levels (i.e., grade 5-7) again for bounded (top) and unbounded (bottom) NLE.
